Another type of separation axioms

By: Jamhour Mahmoud AL-Obaidiy
Dep. of Math, College of Basic Education ,University of Diyala

Key words and Pharases : semi closed (open)set , s-closed (s-open) sets, S-separation axiom .

Abstract:

The main purpose of this paper is to study properties of semi-closed(open) sets s-closed (s-open)sets and generlized -closed(open)sets g-closed(g-open)sets and study the relationship between them.And also inroduce another type of separation axioms called it S- separation axiom and the characteristics that can be prserved of some type of functions on many spaces as S-T_0 , S-T_1 , S-T_2 and we explain that the property of S-T_0 , S-T_1 , S-T_2 are toplological property if the function is injactive and s^*-open .

1- **Intoduction**:

The concepts of semi closed(open) sets s-closed(s-open)sets are intoduction by Levine.N in 1963 [7]. He definned a set A in a topological space X to be s-open set if for some set G, $G \subseteq A \subseteq cl(A)$, wher *cl(A)* denoted to the cloure of a in X . A set F is s-closed if it's complment is s-open set.

In 1970 Levine .N [8] introduced another concepts called it generlized closed (open) sets g-closed(g-open) sets in order to extend many of the important properties of closed set to larger family.

In 1971 Crossieg . S.G and Hildebrand .S.K , introduced the the concept of semi cloure ane they define it, the semi closure of a set A in a topological space X is the smallest semi closed (s-closed) set containing A [4],and denoted it by *scl(A).*

In 1982 Malgahan introduce g-closed function s concept and give some theorems of preservation of normality and regularity [9].

In this paper we continue to study of s-closed set and study the relation between s-closed set and g-closed set ,and proved they are independent conceptes, and give a new notation of semi separation axioms (S-separation axiom) and characteristic that can be preserved of some type of function on many spaces , as S-T_0 , S-T_1 , S-T_2 .

Also we will study the relation between the usual sepration axiom and

S-separation axiom .

2- **Preliminaries:**

In this section we give definitions, remarks, examples and also we prove some results on s-closed(s-open) sets .

Definition (2-1): [7]

Let X be a topological space , $A \subseteq X$, A is called semi closed set (s-closed set) if there exist F closed set in X such that

$Int(F) \subseteq A \subseteq F$ Where *Int(F)* denoted to interior of F.

Definition (2-2): [4]

Let X be a topological space , $A \subseteq X$, A is called semi closed set (s-closed set) if $Int(cl(A)) \subseteq A$.

Remark (2-3) : [5]

The two above difintion (2-1),(2-2) are equivalence .

Remark (2-4) : [1]

The complemant of semi closed(s- closed) set is called semi open (s-open) set.

Remark (2-5) : [1]

Every open set is s-open set but the converse may be not true as following example .

Example (2-5):

Let X={1,2,3} , $T = \{\phi, X, \{1\}, \{1,2\}\}$ is topology on X .

Clear the s-open set in X are $\{\phi, X, \{1\}, \{1,2\}, \{1,3\}\}$.

Hence {1,3} is s-open set but it is not open set.

Definition (2-6): [8]

Let (X,T) be a topological space , $A \subseteq X$ is called g-closed set if *cl(A)* $\subseteq O$ whenever $A \subseteq O$, *O* is open set in X . The complemant of g-closed set is g-open set.

Remark (2-7) :

Every closed set is g-colsed set but the convers my not be true as the following example .

Example (2-8):

Let X={a,b,c,d} , $T=\{\phi, X, \{a\},\{b\},\{a,b\},\{b,c,d\}\}$, is topology on X. Let A={c} , *cl(A***)** ={c,d} , hence A is g-closed set but it is not closed set .

Remark (2-9) :

The intersection of two s-open set not may be s-open set as the following example:

Example (2-10):

Let (R , T_u) is usuale topology .
Clear that (0,5] and [2,7) are two s-open sets in (R , T_u) ,
but it's intersection [2,5] is not s-open set in (R , T_u) .

Theorem (2-11): [6]

If A is s-open set in X and U is open in X then U$\cap$A is s-open in U.

Theorem (2-12):

IF F is closed set and B is s-closed set in X ,then F$\cup$B is s-closed set.

Proof:

Let (X,T) be a topological space ,and let F is closed set and B is s-closed set in X . $\therefore$ F^c is open set in X , B^c is s-open set in X . then $F^c \cap B^c$ is s-open set in X [theorem 2-11]

But $F^c \cap B^c = (F \cup B)^c$ Demorgan's law. $\therefore$ $(F \cup B)^c$ is s-open in X .

Hence F$\cup$B is s-closed set in X (**Remark (2-4)) .** □

Definition(2-13):[1]

A function $f : X \rightarrow Y$ is called :

a- S-open (S-closed) function if $\forall G \subseteq X$ is open (closed) then *f(G)* $\subseteq$ *Y* is s-open (s-closed).

b- S^*-open (S^*-closed) function if $\forall U \subseteq X$ is s-open (s-closed) then *f(U)* $\subseteq$ *Y* is open (closed).

c- S^{**}-open (S^{**}-closed) function if $\forall U \subseteq X$ is s-open (s-closed) then *f(U)* $\subseteq$ *Y* is s-open (s-closed).

3- The Main Result:

In this section we will study the relation between the concepts s-closed and g-closed sets and we will show that there are two independent concepts completely through the following four examples:

The following example show that there exist g-closed set and s-closed set at the same time.

Example (3-1) :

Show in example (2-8) the set A={c} , *cl(A)* ={c,d} , hence A is g-closed set , and it's s-closed set because if F={c,d} is closed set , then $int(F) = \{\phi\} \Rightarrow \phi \subseteq \{c\} \subseteq \{c,d\} \quad \therefore \text{int}(F) \subseteq A \subseteq F$

Hence A ={c} is g-closed set and s-closed set at the same time.

The following examlpe show that there exist some sets are g-closed set but it is not s-closed set.

Example (3-2) :

Let X={a,b,c} , $T = \{\phi, X, \{a\}, \{a,b\}\}$ be topology on X .

Let A={a,c} , A is g-closed set but it is not s-closed set.

The following examlpe explain that there exist some sets are s-closed set but it is not g-closed set.

Example (3-3) :

Let (R,T_u) be the usual topology on R , let A=[0,1) clearly A is s-closed set but it is not g-closed set because

If O = (-1,1) open interval in R , show that $A \subseteq O$ but $cl(A) \not\subset O$

Hence A is not g-closed set .

The following examlpe show that there exist some sets that are not s-closed and are not g-closed set.

Example (3-4) :

In the example (2-8) ,let A={a,b} , clear that $cl(A)=X$, $int(cl(A)) = X$ show that A is not s-closed set because $int(cl(A)) = X \not\subset A$.

And it is not g-closed set too because $A \subseteq \{a,b\}$ but $cl(A)=X \not\subset A$.

Hence we can say that the s-closed set and g-closed set are independent completely consepts.

4- S –T_0 space

Definition (4-1):

A topolgical space X is called S-T_0 space if and only if for each x and y are distinct points in X , there exist an s-open set W in X contaning one of them and not the other .

Remark (4-2):

Every T_0 space is S-T_0 ,but the coverse may not be true as the following example .

Example (4-3):

Let X={1,2,3} and let T={ $\phi, X, \{1\}$ } be a topology on X , clear (X,T) is S-T_0 space because the s-open sets in X are : $\{\phi, X, \{a\}, \{b\}, \{c\}, \{a,b\}\{a,c\}\}$, hence every two distinct point in X , there exist s-open set in X contaning one of them and not the other, and it is not T_0 space . Note that b and c are two different points in X , and we can't find an open set in X which contains one of them and not the other. Then X is S-T_0 space but it is not T_0 space.

Theorem (4-4) :

Every open subspace of S-T_0 space is S-T_0 space.

Proof

Let Y be an open subspace of S-T_0 space X , and let x , y be two distinct point of Y , then there exist an s-open set A in X containing one of them and not the other, let it be containing x but not y then $A \cap Y$ is s-open set in Y [theorem(2 – 11)] containing x but not y .

Hence Y is S-T_0 space .

Thorem (4-5) :

Let $f : X \rightarrow Y$ be injective function and S^*- open function , If X is S-T_0 space then Y is S-T_0 space.

Proof

Let y_1 , y_2 be two distinct points in Y , since f is injective function then there exist two distint points x_1 , x_2 in X . such that $y_1 = f(x_1)$, $y_2 = f(x_2)$, but X is S-T_0 space and x_1 , x_2 are two distinct point in it , then there exist g-open set V in X containing one of them and not the other (i.e $x_1 \in V$, $x_2 \notin V$) then $f(x_1) \in f(V)$ and $f(x_2) \notin f(V)$.

since f is S^*- open function and V is s-open set in X , then $f(V)$ is open set in Y . $\therefore$ $f(V)$ is s-open set(remark 2-5), since $y_1 = f(x_1)$, $y_2 = f(x_2)$ then $y_1 \in f(V)$, $y_2 \notin f(V)$. Hence Y is S-T_0 space .

Corollary(4-6):

S-T_0 is a topological property where the function is injective and S^*-open function .

5- S -T_1 space

Definition (5-1) :

A topological space X is called S-T_1 space if and only if for each
x and y are distinct point in X there exist two s-open sets G_1 , G_2
in X such that $x \in G_1$, $y \notin G_1$ and $x \notin G_2$, $y \in G_2$.

Remarks (5-2):

a. Every S-T_1 space is S-T_0 space .
b. Every T_1 space is S-T_1 space , but the converse my not be true as in the following example .

Example (5-3):

Let X= { 1,2,3} , T = $\{\phi,\{1\},\{2\},\{1,2\}\}$ be topology on X , then the space X is S-T_1 but not T_1 space.

Theorem (5-4):

A topological space X is S-T_1 space if and only if $\forall x \in X$, singleton {x} is s-closed set in X.

proof : $\Longrightarrow$

Let X be S-T_1 space and let $x \in X$, to prove that {x} is s- closed set we will prove X-{x} is s-open set in X , let $y \in$ X-{x} $\Longrightarrow$ $x \neq y \in$ X, and since X is S-T_1 space then their exist two s-open sets G_1 , G_2 such that $x \notin G_1$, $y \in G_2 \subseteq$ X-{x}. since $y \in G_2 \subseteq$ X-{x} then X-{x} is s-open set , Hence {x} is s-closed set.

$\Longleftarrow$ conversely:

Let $x \neq y \in$ X then {x},{y} are s-closed sets ,
i.e X-{x} is s-open set clearly $x \notin$ X-{x} and $y \in$ X-{x}.
simlarly X-{y} is s-open set , $y \notin$ X-{y} and $x \in$ X-{y}.
Hence X is S-T_1 space.

Theorem (5-5):

Let X be S-T_1 space and $f : X \rightarrow Y$ be an injective function and S*- open function then Y is S-T_1 space.

Proof:

Let y_1 , y_2 be two distinct points in Y , since f is injective function , then there exist two distinct points x_1 , x_2 in X , such that $y_1=f(x_1)$, $y_2=f(x_2)$, but X is S-T_1 space and x_1, x_2 are distinct points in it ,then there exist two s-open sets V_1 , V_2 in X such that $x_1 \in V_1$, $x_2 \notin V_1$ and $x_2 \in V_2$, $x_1 \notin V_2$.
(i.e $f(x_1) \in f(V_1)$, $f(x_2) \notin f(V_1)$ *and* $f(x_2) \in f(V_2)$, $f(x_1) \notin f(V_2)$).

Since f is S*-open function and V_1,V_2 are two s-open set in X then $f(V_1)$, $f(V_2)$ are two open sets in Y (Def 2-13-b).
Hence $f(V_1)$ and $f(V_2)$ are s-open sets in Y , but $y_1 = f(x_1)$ and

$y_2 = f(x_2)$ then $y_1 \in f(V_1)$, $y_2 \notin f(V_1)$ and $y_2 \in f(V_2)$, $y_1 \notin f(V_2)$.

Hence Y is S-T_1 space.

Corollary(5-6):

S-T_1 is a topological property where the function is injective and S^*-open function .

Theorem(4-7):

Every open subspace of a S-T_1 space is S-T_1 space.

Proof :

Let X be S-T_1 space and let G be an open subspace of X ,

let x $\in$ G , since X is S-T_1 space , X-{x} is s-open set in X.

G $\cap$(X-{x}) = G-{x} and it is s-open set in G [Theorem 2-11]

Then {x} is s-closed in G.

Hence G is S-T_1 space [Theorem 5-4].

6- S – T_2 space ((S – Hausdorff space))

Defintion (6-1):

A topological space X is called S-T_2 space (S-Hausdorff) ,

if $\forall x_1 \neq x_2 \in X$, $\exists$ two s-open sets H_1 , H_2 in X such

that $x_1 \in H_1$ and $x_2 \in H_2$ and $H_1 \cap H_2 = \phi$.

Remarks (6-2) :

1- Every S-T_2 space is S-T_1space .

2- Every T_2 space is S-T_2 space , but the converse may not be true as the following example.

Example (6-3) :

Let X={a,b,c} , T_i is indiscrete topology on X , then (X, T_i) is S-T_2 space but it is not T_2-space .

Theorem (6-4):

Every open subspace of S-T_2 space is S-T_2 space.

Proof :

By the same method in proveing theorem (5-7)

Remark (6-5):

Every singleton subset of S-T_2 space is S-closed set.

Theorem (6-6)

Let X be S-T_2 space and $f : X \to Y$, be injactive , S^*-open

function , where X and Y are topological spaces then Y is
S-T_2 space .

Proof:

Let y_1,y_2 be two distinct points in Y , since *f* is injective function , then there exist two distinct points x_1,x_2 in X ,such that $y_1=f(x_1)$,
$y_2=f(x_2)$, , but X is S-T_2 space and x_1 , x_2 are distint point in it,
then there exist two s-open sets H_1,H_2 in X such that $x_1 \in H_1$,
$x_2 \in H_2$ amd $H_1 \cap H_2 = \phi$ since f is S^*-open function then $f(H_1)$ and $f(H_2)$ are S-open sets in Y ,but $y_1 = f(x_1)$ then $y_1 \in f(H_1)$,
since $x_2 \in H_2$ then $f(x_2) \in f(H_2)$, but $y_2 = f(x_2)$ then $y_2 \in f(H_2)$,
to prove that $f(H_1) \cap f(H_2) = \phi$, since $H_1 \cap H_2 = \phi$ then $f(H_1 \cap H_2) = \phi$ then $f(H_1) \cap f(H_2) = \phi$.

Hence Y is S-T_1 space.

Corollary (6-7):

S-T_2 is topological property where the function is injective and S^*-open function .

Proof:

Clear frome theorem (6-6)

The following diagram shows the relation between usual separation axiom and S-separation axiom :
