Abstract:

Background: Matrix metalloproteinases (MMPs) are a family of extracellular matrix degrading proteinases are involved in tumor invasion, metastasis as well as in the early stages of carcinogenesis, the aim of this study was to explore whether changes in matrix metalloproteinase-9 (MMP-9) are involved in the urinary bladder cancer.

Methods: Expression of MMP-9 was evaluated in the tumor of 30 urinary bladder cancer cases and 20 control group with in situ hybridization.

Results: Increased expression of MMP-9 was significantly higher in tumor compared with normal samples. Expression of MMP-9 did not found any significant association with tumor age, sex, grade and muscle invasion.

Conclusion: This study shows that MMP-9 may play an essential role in the determination of bladder cancer.

Keywords: MMP-9, Bladder carcinoma

Introduction:

Bladder cancer when superficial has a good prognosis but it has a high recurrence risk and about 10–15% of the superficial carcinomas will progress into muscle invasive or metastatic type (1). The most powerful factor for predicting the behavior of bladder carcinoma is the stage of the tumor. One of the essential alterations that occur in malignancy is tissue invasion and metastasis (2). The metastatic process involves intravasation and extravasation of tumor cells, followed by reimplantation of tumor cells, formation of a new tumor stroma, and neoangiogenesis to consolidate a secondary tumor at a distant site (3). Degradation of the extracellular matrix and components of the basement membrane by proteases facilitates the detachment of tumor cells, their crossing of tissue boundaries, and invasion into adjacent tissue compartments (2).

The importance of tumor-associated proteases in invasion and metastasis has been demonstrated for a variety of solid malignant tumors (4).

Matrix metalloproteases (MMPs) comprise a family of proteolytic enzymes that have been implicated in tumor growth, invasion and metastasis in experimental cancer models and in human tumors (5). Two members of this family in particular, MMP-2 and MMP-9, degrade type IV collagen, fibronectin and laminin, major components of the basement membrane and are commonly used as markers of the malignant phenotype. MMP activity is regulated by a group of four distinct tissue inhibitors of metalloproteases (TIMPs) (6).

Matrix metalloproteases are characterized by a zinc atom at the active site and are classified according to homologies in sequence and substrate affinity (7). One of the first observations that suggested a role for MMP-9 in tumor invasion relates to the fact that the release of MMP-9 is associated with the metastatic phenotype of transformed rat embryo cells (8).

Matrix metalloproteases-9 (Gelatinase B, 92kDa type IV collagenase) was first purified from human macrophages (9). MMP-9 expression is limited to osteoclasts, macrophages, trophoblasts, hippocampal neurocytes and migrating keratinocytes and it is controlled by growth factors, chemokines and other stimulatory signals (10). MMP-9 is secreted as an inactive precursor form, proMMP-9. It forms a tight complex with TIMP-1 and TIMP-3. The complex of proMMP-9 and TIMP-1 is a potential inhibitor of MMPs (11). Another activation mechanism is plasminogen/MMP-3 mediated activa-
tion. Plasmin can also directly activate proMMP-9 (10). The role of MMP-9 is, however, not that clear particularly in bladder cancer (12). The results have also been conflicting in other types of cancer and the expression of MMP-9 has been linked to both favorable and poor prognosis (13).

The aim to explore whether MMP-9 is involved in urinary bladder cancer and to investigate the association between tumor MMP-9 and the clinicopathological features of bladder cancer and MMP-9 as a prognostic marker in bladder carcinoma.

Material and Methods:

Thirty urinary bladder carcinoma with paraffin embedded tissue samples were obtained from the files of the Department of Pathology at Al-Yarmouk and Baghdad Teaching Hospital. In addition 20 apparently normal bladder autopsies were collected from the Forensic Medicine Institute archives. The samples were evaluated by a pathologist to represent the carcinoma of the bladder. The histological grade of the tumors was reviewed and classified according to the WHO Classification for urological tumors. The median age of the patients was 59 years (49-82). The clinical stage was defined according to the 1997 International Union against Cancer staging system.

In situ hybridization (ISH) for detection of MMP-9 gene.

The use of Biotin – Labeled DNA probe for mmp-9 / DNA (Maxim Biotic, USA) 216bp, MMP-9 (8 μg/100 µl) litter dd H2O (Maxim Biotech, Inc., U.S.A).

In situ hybridization (ISH) is a technique makes use of the high specificity of complementary nucleic acid binding to detect specific DNA or RNA sequence in the cell. For detection of this markers, the biotinylated DNA probe hybridize to the target sequence (mmp-9 mRNA sequence) then a streptavidin–AP (streptavidin-alkaline phosphatase) Conjugate is applied followed by addition of the substrate promo-chloro–indolyl–phosphatel / nitro-blue tetrazolium (BCIP/NBT) which yield an intense blue – black signal appears at the directly specific site of the hybridized probe. This streptavidin – Ap conjugate like the biotinylated probe provides a rapid and highly sensitive detection method. Hybridization / Detection System will give an intense blue–black color at the specific sites of the hybridization probe in both positive test tissues. Evaluation of the in situ staining was done with assistance of a histopathologist.

Scoring

A scoring system that includes evaluation of the staining percentage of stained bladder cells was employed for the expression of MMP-9. Counting the number of the positive cells in the bladder tissue which gave a blue-black nuclear staining under the light microscope. The extent of the ISH signaling the cells of the examined tissue was determined in 10 fields under high power microscope (100X). In each field, the total staining score divided by the number of whole cell per field in 10 fields, so the percentage of positively stained cells in the 10 fields was calculated for each case by taking the mean of the percentage of the positively stained cell in the 10 fields. Tissues were regarded MMP-9 positive when their ISH signaling scores were ≥ 5% (10).

Statistical analysis: The associations between the presences of MMP -9 in different groups were assessed by the Chi-square test. P value of <0.05 was considered statistically significant.

* Significant at the < 0.01 level.
A pooled analysis of the positivity of the different expression in tissue is presented in Table 2. There was no statistically significant between MMP-9 positivity and sex or age (P>0.05).

Also, there was no significant difference between the overexpression of MMP-9 and tumor grade or with muscle invasion (P>0.05).

Discussion:

Bladder carcinoma is one of the most common urologic malignancies occurring worldwide (14, 15). Matrix metalloproteinase - 9 (MMP-9) has been associated with tumor cell invasion and metastasis in many human cancers, including bladder cancer. As a marker for elevated urinary mRNA levels of MMP-9 are associated with cancer (16). High MMP-9 levels were significantly correlated with large tumor size and poor malignancy grade, and increasing levels were associated with poor overall survival (17).

Our results revealed high frequency of MMP-9 activities in bladder cancer cases as compared to control (p<0.001). 70% of the urinary bladder carcinomas, showed an overexpression (>50%) of MMP-9 mRNA. MMP-9 degrades type IV collagen, the major component of the basement membrane (18). Studies that measured urinary MMP-9 by ISH have suggested that MMP-9 levels demonstrated that urinary MMP-9 levels were significantly elevated in bladder cancer subjects by ISH analysis (19). Several independent studies as well as our present study have consistently reported elevated MMP-9 activity in urine samples from patients with bladder cancer which provided the rationale to test MMP-9 as a screening of diagnostic marker (20).

Here, MMP-9 positivity did not correlate to the age, sex, grade and muscle invasion of the tumor not observed. In other studies by different investigators, correlation with clinicopathological parameters varies (21, 22). The results were consistent with of the study who did not found any relation between the expression of mmp-9 in bladder carcinoma tissue with clinicopathological feature (23).

One explanation for the discovery in the present study of MMP-9 may be the possible role of MMP-9 in immunological host reactions in cancer patients or controlling tumor angio-genesis. It is possible that these factors might dominate in early tumor progression (24). MMP-9, similarly to other MMPs, is produced as an inactive, latent form that requires activation for being enzymatically active Stromelysin-1 (MMP-3) is one of the most effective activators for MMP-9 (25).

Earlier studies showed the potential importance of these enzymes in tissue culture and animal models of invasion and metastasis (26, 27). MMP-9 similarly to other MMPs is produced as an inactive, latent form that requires activation for being enzymatically active (27).

MMP-9, may participate in the inhibition of endothelial cell proliferation and angiogenesis. This is due to the fact that MMPs, including MMP-9, generate antiangiogenic endostatin-containing peptides from collagen XVIII (28). In the present study, we did not find a statistical correlation between MMP-9 staining and tumor grade or stage. This is in line with Durkan et al. who also did not found any correlation between MMP-9 staining and histological grade and stage (28).

In addition other MMPs such as MMP-2, MMP-7 and MMP-13 and some serine proteases are able to activate proMMP-9 (29). MMPs are known to be needed in degradation of extracellular matrix and basement membranes, but they also play a role in the formation of new capillaries, which is essential for tumor progression. MMP-9 is transcriptionally regulated by inflammatory cytokines such as tumor necrosis factor and interleukins (30).

Conclusion:

We have found that MMPs overexpression in urinary bladder carcinomas associated with better prognosis and might have adiagnostic value but a further studies are needed to confirm this finding.
