Date of acceptance 31/3/1998

Abstract

Positron annihilation lifetime has been utilized for the first time to investigate the free – volume hole properties in thermoluminescent dosimeter (TLD) as a function of gamma-dose. The hole volume, free volume fraction determined form orthopositronium lifetime are found to be dramatically increase to large values, and then to minimum values as a function of gamma-dose. The free – volume holes size is found to be 0.163nm³ and to have maximum of 0.166nm³ at the gamma-dose of 0.1 and 0.8 GY, respectively.

Introduction

Studies of the microstructure free- volume properties at a molecular and atomic scale can provide a basic understanding of the mechanical and physical properties of polymers(1). In PAL technique [2], one employs the positron emitted from a radioactive source as a probe to monitor the lifetime of the positron and positronium (Ps) (a bound atom consists of an electron and a positron) in polymer material under study. Because of the possitive -charged nature of the positron, the positron and the positronium atom are attracted by the core of electrons of the polymers and trapped in open spaces like holes voids, or cavities. The annihilation photons come mainly from these open spaces. Positrons are commonly produced by positron radioactive isotope, such as ²²Na. The Ps atom formed can be in the singlet (P-Ps) or triplet state (o-Ps), with mean lifetime in free spaces of 0.125 ns and 140 ns, respectively. In condensed medium the mean lifetime of o-Ps is considerably reduced to a few nanosecond [3] due to its interaction with surrounding molecules of the medium. The results for o-Ps lifetime and its probability are related to free-volume hole size (Vh), fractional free volume (Fh) and distribution. The relation between the mean radius of free–volume hole size and the o-Ps lifetime \( \tau_{o-Ps} \) was found according to the semi –empirical formula (4):

\[
\tau_{0-Ps} = 0.5 \left( \frac{1 - \frac{R}{R_o}}{0.159 \sin \left( \frac{2\pi R}{R_o} \right)} \right)^{-1} \text{ns} \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots
\]

where \( R = R_o + \Delta R, \Delta R \) is the electron layer thickness. The free-volume –hole size \( V_h \) is:

* Dr.-Physics, Department - College of Science - University of Baghdad
\[ V_h = \frac{4}{3} \pi R^3 \].................................(2)

The fractional free volume (the ratio of the free volume to the total volume) was found according to fitted empirical formula [5,6] as:

\[ F_h = AV_h I_{0-P_s} \].................................(3)

where \( A \) is a constant, its value is between 1-2 for polymer, \( V_h \) is the free-volume hole size and \( I_{0-P_s} \) is the intensity of \( \tau_{0-P_s} \). PAL is widely used for investigation different aspects of polymer properties [6-11]. Positron and positronium lifetime in polymer material may affected by different factors such as changing in degree of crystallinity, blending of polymer, plasticization of polymer aging of polymer, temperature, irradiation of polymer [12-20]. When an organic materials such as polymer is irradiated by neutron-flux, different processes can take place in the materials according to the energy of the neutron. Within the reaction with the nuclei of the atoms of the irradiated medium, Fast neutrons transfer a considerable amount of their energy. Each struck nucleus is ejected as a recoil ion that interact with orbital electrons of the medium, thus production molecular excitation and ionization. The initial neutrons are degraded to a thermal-energy state as a result of the several scatterings. Irradiation effects on PTFE were studied by kindl et al [16] using gamma –irradiation in the dose range up to 200 kGy. They found that \( \tau_{0-P_s} \) life to be decreased with increasing \( \gamma \)-dose as a result of increasing crystallinity and radicals quenching .Kindl[17] found that free radicals on the one hand and irradiation induces structure alterations on the other hand change the positron lifetime parameters within the irradiation dose range up to 200 kGy. The studies of Consolati and Quasso [19] showed that the longest lifetime component is certainly due to \( \alpha \)-Ps “Pick off” annihilation. Recently Al-Bayati [20] found that \( \gamma \)-irradiation induces structural changes in PTFE, increasing crystallinity in the amorphous regions within the irradiation dose up to 887 kGy. Despite of numerous studies on positron annihilation lifetime in polymers to the best of our knowledge no one investigate the effect of absorbed dose on TLD structure, hence on its efficiency for absorbed dose measurement. Therefore the present work is the first attempt to study the effect of \( \gamma \)-dose on \( V_F \) and \( F_r \) of TLD, hence TLD structure.

**Experimental Procedure and Data Analysis**

The position lifetime measurement were conducted using fast slow coincidence system, have a time resolution of 340 ps. The position source consisted of 12 \( \mu \)Ci of \( ^{22} \)NaCl placed between two aluminum foils of 5 \( \mu \)m thickness the fraction of positrons absorbed in the source was found to be 8% using the recent formula of Al-bayati [12] :

\[ \alpha, / \rho = 27.84Z^{0.137} \] . The TLD samples used for present study, are the same as those used as irradiation dosimetry, (it contains 70% PTFE and 30% LiF) with diameter of 1.3 cm and thickness of 0.1 mm supplied by Vienten. The irradiation was done with CO-60 in air at R.T., with a dose rate of 0.1 Gy/min up to a total dose of 2Gy . The lifetime spectra were measured for each individual dose value with a total integral counts of \( 2 \times 10^5 \). The peak – to – background ratio was better than 2300:1. The lifetime spectra were analyzed in three-lifetime components using PFSFIT program [21] include two components for source correction.
The lifetime components, their relative intensities and the parameters of the prompt curve, were simultaneously fitted.

**Results and Discussion**

The average radius of the free-volume hole, the free volume hole size and the free volume fraction, were calculated using equations (1) and (2), respectively. The o-ps lifetime ($\tau_3$) and the second lifetime ($\tau_2$), free volume $V_f$ and free volume fraction ($F_f$) were plotted as a function of $\gamma$-dose in Figs.(1), (2) and (3), respectively. It is clear that ($\tau_2$), which is related to free positron annihilation, and which its decay depends less on the structural state of the polymer, was found to be $\gamma$-dose independent, because no influence of $\gamma$-dose is expected on the mean electron density. The longest lifetime component $\tau_3$, which is due to o-ps "pick off" annihilation was found to be 2578 ps for unirradiated samples, corresponding to $V_f$ of 0.154 nm$^3$ and $F_f$ of 0.94%. The behaviour of $V_f$ and $F_f$ with $\gamma$-dose can be divided into two stages as shown in Figs.(1), (2) and (3). In the first stage up to 0.8 Gy, the $V_f$ hence $\tau_3$ and $F_f$ increase with increasing dose and reached an increment of 6.1%, 3.4% and 2.7%, respectively at 0.1 Gy, then reached a maximum increment of 8.0%, 4.4% and 20%, respectively for $V_f$, $\tau_3$ and $F_f$ at 0.8 Gy. In the second stage between (0.8 and 2) Gy, $V_f$ hence $\tau_3$ and $F_f$ begin to decrease gradually with increasing dose and reached a minimum increment of 1.41, 0.7% and 1.9% respectively. These results suggest that $\gamma$-induces structural changes in TLD resulting in degradation of TLD chains during the first irradiation stage, which causes an increase of the three parameters. As the dose increases above 0.8 Gy, the effective free radicals induced by $\gamma$-irradiation, and increasing crystallinity in the amorphous regions of TLD samples, resulting in reduction of free volume fraction, free volume hole size, hence o-p, lifetime.
Conclusion
Degradation of TLD chains caused by gamma - irradiation results in an increment of 10% and 25% per Gy in $V_r$ and $F_r$, respectively, which may reduce significantly the efficiency of TLD for the received dose measurement for each usage.

دراسة زمن عمر فناء البوتزترون لتغيرات الحجم الحر
في مقياس الوميض الحراري الضوئي المشع بكاما

د. عبد الحسين عبد الأمير البياتي
قسم الفيزياء – كلية العلوم – جامعة بغداد

خلاصة

تم استخدام زمن عمر فناء البوتزترون لأول مرة لدراسة خصائص الحجم الحر في مقياس الوميض الحراري الضوئي كمالة لمجرة. فقد وجد بان الحجم الحر والحجم الجزئي المعين من زمن عمر البوتزترون بزيادة بعلاجات لقيم عالية وتعتبر شائعة لقيم متدنية كمالة لمجرة. ووجد بان الحجم الحر ذات
القيمة 131.5 نانومتر مكعب له قيمة عظمى في 166.5 نانومتر مكعب عند جرع كاما 1.1 و 0.8،
كراي على التوالي.
