The Prevalence of Cutaneous *Tricophyton* Spp in Patients with Skin Mycosis in Babylon Province

salah Mehdi Hasan
College of Health & Medical Technology

ABSTRACT

**Background:** *Trichophyton* is a *keratinophilic* filamentous fungus which has the ability to invade keratinized tissues thus; it is considered as one of the leading causes of hair, skin, and nail infections in humans. Most of the *Trichophyton* species have teleomorphic forms and these teleomorphs are classified under genus *Arthroderma*.

**Objective:** The present study aimed to determine the prevalence of *Tricophyton* spp. infection among patients with skin mycosis in Alhella, the center of Babylon Province.

**Subject and Methods:** During the period from Oct. 2010 to May. 2011, a total of 972 specimens (Skin scraping and nail were collected from patients attending the out-patient clinic for dermatology and venereal diseases in Babylon General Hospital. Direct microscopical examination and culture were done for specimens. Identification of *Tricophyton* spp. based on standard cultural and biochemical criteria. All data were statistically analyzed according to Chi-Square and Kolmogrov-smirnov (P<0.05).

**Results:** The results revealed that 753 (77.5%) patients were clinically and laboratory confirmed as having skin mycosis, 197 (26.2%) of them have *Tricophyton* infection. The prevalence of *Tricophyton* infection was significantly higher in folded skin 124 (62.9%) compared to other body sites and in females compared to males (66.5% vs. 33.5%). Additionally, the highest prevalence was recorded in 12-21 years age group, and there was non-significant difference in the infection rate regarding the residence.

**Conclusion:** *Tricophyton* constitutes about one quarter of skin mycoses infections in Babylon Province, so must raise awareness of health and increase health education among people and make them be known of the diseases which are caused by fungi and their danger, and the importance of diagnosing them as early as possible and to treat them and control their spread, make independent units in the hospital Laboratory to diagnose the fungal diseases and send specialized medical groups to the endemic areas with the fungal diseases.

**Key words:** Skin mycoses, *Tricophyton*, Cutaneous, Babylon

INTRODUCTION

There are twenty – seven species under genus *Trichophyton*. Most common are *Trichophyton concentricum*, *Trichophyton mentagrophytes*, *Trichophyton rubrum*, *Trichophyton schoenleinii*, *Trichophyton tonsurans*, *Trichophyton verrucosum*, and *Trichophyton violaceum*. *Trichophyton* is a *keratinophilic* filamentous fungus which has the ability to invade keratinized tissues thus; it is considered as one of the leading causes of hair, skin, and nail infections in humans. Most of the *Trichophyton* species have teleomorphic forms and these teleomorphs are classified under genus *Arthroderma*. Growth rate may range from being slow to moderately rapid, and colonies are waxy, glabrous, downy to cottony; and surface colony color ranges from white to bright yellowish beige or red violet and the reverse may be pale, yellowish, brown, or red – brown. Hyphae appetite *hyaline*, *septate hyphae*, microconidia, macroconidia, and
conidiophores, and arthroconidia are present, chlamydospores may also be produced. Conidiophores are little differentiated from vegetative hyphae. **Microconidia** are unicellular, round - to pyriform – shaped, numerosely present, may be solitary or arranged in grape – like clusters.\[^5\]. Macroconidia are multicellular (with two or more cells), may either be smooth thin or thick – walled, cylindrical, club – shaped, or cigar – shaped, and are often absent; and several species are typically sterile; however, sporulation may be induced with the use of an appropriate media\[^5\]. The fungi can cause tinea pedis, tinea cruris, tinea corporis, and onychomycosis. The infection spreads by contact, especially in gyms and showers.\[^6,7\] The infection can be stopped by bathing with soap and water and applying an appropriate fungicide.\[^7\] The treatment generally, amorolfine, clotrimazole, itraconazole, ketoconazole, naftifine, and terbinafine are general active in vitro against Trichophyton species. Terbinafine usually shows to be the most effective agent. Isolates of Trichophyton rubrum are more vulnerable to antifungal agents compared to Trichophyton mentagrophytes. Also active in vitro against Trichophyton species are the azole derivatives, Syn 2869, Syn2836, Syn2903, and Syn2921\[^8\]. Terbinafine and itraconazole are commonly used now in treatment of infections caused by Trichophyton species compared to griseofulvin which is once the drug of choice for dermatophytosis treatment\[^9\]. However, due to the availability of more effective and less toxic drugs griseofulvin is now less commonly used. Oral therapy is usually preferred for treatment of tinea capitis and onychomycosis\[^7,10\]. The study aimed to determine the spread of superficial – cutaneous Tricophyton in Babylon province, we had done the Isolation, identification, and description of main species that cause the superficial – cutaneous Tricophyton\[^10\].

**MATERIALS AND METHODS**

During the period from October /2010 to April / 2011, a total of 972 specimens (skin scraping and nails) were collected from patients attending the out-patient clinic of dermatology and venereal diseases in Babylon General Hospital. All specimens were examined microscopically by direct mount with 10% potassium hydroxide and lactophenol blue stain Beiträgen (2010)\[^1\]. Culture of specimens was done on Sabouraud's Dextrose Agar using direct microscopy of lye-treated material and cultivation on glucose peptone agar with examination of the cultures for microcolonies of Trichophyton verrucosum after 2-4 days incubation. Identification of Tricophyton based on colonial morphology, on corn meal agar, as well as the form of the hyphae Screened under the microscope Isolation 92010)\[^9\]. All data were statistically according Chi-Square and Kolmogrov-smirnovz (P<0.05) Ebraheem (2006)\[^18\].

**Results:**

The distribution of infection according to age groups showed that a significant differences (P>0.05) although the highest infection rate was recorded in age group of (12-21) years compared with other age groups Table (1)

**DISCUSSION**

Trichophyton refers to a group of *fungi* that can infect humans, animals, and soil. There are a multitude of different fungal species that are classified within the genus *trichophyton*. There are, however, only a few of these that actually infect humans Carin (2008) [4]. These fungi feed on keratin — a protein found in the skin. As a result, they cause a variety of ailments, including athlete’s foot, *ringworm*, *jock itch*, fungal nail infection, *tinea* barbae, *tinea capitis*, and majocchi granuloma. The specific fungus that most commonly causes athlete’s foot is called *trichophyton rubrum*. These fungi thrive in areas that are warm and moist. They can grow in socks, shoes, wet floors, and other soggy environments Beiträgen (2010) [1]. The overall prevalence obtained in the present study was 26.2%, which is in agreement with those reported by other studies; 27.8% in Babylon Mahmmd (2000) [14]. The results revealed that the highest infection rate among those with 12-31 years old. This probably related to the work style of those people, and exposed to contaminated water in the marshes, and farm. Federman (2001) [12]. The significantly higher infection by coetaneous *Tricophyton* infection in females 131 (66.5) compared to males 66 (33.5) in the present study was consistent with those reported by Ella- bid and Khalifa (2001) in Libya [16]. This probably due to exposure of female hands to longer periods of humidity during homework including washing of cloths and dishesFurthermore, females frequently use acetone as nail polish removal beside exposure to other chemicals such as detergents cracks the superficial layer of nails predisposing them for *Tricophyton* infection [11]. Males were the most frequency isolated species causing in the results of coetaneous Tricophyton, nails and hair infection among the skin fungi infections in Babylon provinceEbraheem (2006) [18]. *Tricophyton*, was the most frequent species caused skin infections, in urban 110 (55.8%) and rural areas 87 (44.2%) Marshlands who infected with superficial – coetaneous mycoses. The predominant site of infection in this study was the skin folds (62.9%), nails (31.5%) and hair (11%). These results were consistent with those reported by Mahmmd,(2000) who found that cutaneous *Tricophyton* is common in skin folds (7.8%) followed by nails (18.1%) and hair areas (12.5%). The predominance of cutaneous *Tricophyton* in skin folds such as axillary, interdigital, inframammary glands areas seems to be not unusual, since these areas provide suitable environment e.g. humidity and warmth for *Tricophyton* growth Mahmmd (2000) [14]. We must recommend to increase health education among peoples and make them be known of the diseases which are caused by fungi and their danger, and the importance of diagnosing them as...
early as possible and to treat them with control their spread, and make independent units in the hospital laboratory to diagnose the fungal diseases and send specialized medical groups to the marshlands areas for diagnosis dissemination of health education Virella(1997)[17].

معدل إنتشار الفطريات الجلدية بين المصابين بالأمراض الفطرية الجلدية في الحلة- محافظة بابل

الخلاصة

الخلفية الدراسية: Tricophyton هو نوع من الفطريات الخيطية المحبة للكرياتين الذي لديه القدرة على غزو الأنسجة المتقرنة وبالتالي، فهو يعتبر واحداً من الأسباب الرئيسية لأصابة البشرة والشعر والأظافر. وسرع الانتشار بين البشر معظم أنواع الفطريات الشعرية، وكذلك تمتلك أنزيمات عديدة وأحماض مثل حامض البروتينيز تعتبر عاملة قوية.

المريض وطرق العمل: أجريت هذه الدراسة لمعرفة معدل إنتشار الفطريات الجلدية بين المرضى المصابين بالأمراض الفطرية الجلدية في مدينة الحلة – مركز محافظة بابل. جمعت النماذج خلال الفترة من تشرين الأول 2010 إلى مايس 2011، ما مجموعه 972 نموذجا (قشط من الجلد أو الأظافر) من المرضى المراجعين لشعبة الأمراض الجلدية والزهرية في العيادة الخارجية لمستشفى بابل العام. فحصت جميع النماذج مجهرياً بالطريقة المباشرة وكذلك بزرعها على الأوساط الزرعية الخاصة. أعتمد تشخيص الفطريات الجلدية نوع الترايكوفايتون على الصفات الزرعية والكيموحيوية. حلت جميع النتائج احصائياً.

النتائج: أظهرت نتائج الفحص السريري والفحوصات المختبرية التوكيدية بأن 757 (77.5%) مريضاً كانوا مصابين بالفطريات Tricophyton، من بينهم 267 (27.5%) مريضاً مصابين بالفطريات الجلدية. أعلى ونسبةً من الأصابة في منطقة بابل، وكانت أعلى في النساء مقارنة بالرجال (77.6%). فضلاً عن ذلك، فإن أعلى نسب الأصابة سجلت في الفئة العمرية 12-21 سنة.

التوصيات: شكلت الأصابة بالفطر Tricophyton ما يقارب ربع المرضى المصابين بالأمراض الفطرية الجلدية في محافظة بابل. إذاً، يجب أن نظرنهم كنسبة من الأمراض التي تسببها الفطريات وخطورتها، وأهمية تشخيصها وعلاجها بسرعة وقتم ممكن السيطرة على انتشارها، وتكوين وحدات مستقلة في مختبرات المستشفى لتشخيص الأمراض الفطرية وإرسال مجموعات طبية متخصصة إلى المناطق الموبوءة للسيطرة على الأمراض الفطرية.

الكلمات المفتاحية: الفطريات الجلدية, Tricophyton, محافظة بابل.
