INTRODUCTION:

Objective: The frequency of bacterial, parasitic and fungal enteropathogens among 596 children and adults patients who attended to Al- Sweara hospital and to health centers in Al- Sweara city were investigated. And the possibility of the influence of some factors such as residence, Sex and Age on the incidence variation of diarrhea and the diversity of its microbial etiology.

Methods: The study achieved from the beginning of November 2013 until the end of September 2014 and involved 596 patients from both sexes and different ages, all stool samples were collected in sterile containers and conducting to macroscopic and microscopic examination and various laboratory tests to determine the type of the causative agent, whether parasitic or bacterial or fungal also an informative questionnaire form was fill for each patient which included age, sex, place of residence and subjected these data for statistical analysis using spss.

Results: Total number of positive samples were 376(63%) of these 177 (47.07%) had parasitic etiology, of which Entamoebahistolytica was found in the majority of cases 100(26.5%) while Giardia lambilarepresent 77(20.4%). Bacteria represent 156(41.4%) which of 49(13.0%) were Escherichia coli, 38(10.1%) were Salmonella species, 36(9.5%) were Shigella species and only 43(11.4) of the samples were positive for yeast. The majority of positive samples in this study 119(31.6) were under the 5 years. While the lost positive samples were 44(11.7) mad up the 46 years old. Male members were affected more than the female, where are the infection percent in male was 200(53.1) while in female 176 (46.8). The rate of positive samples was 143(23.9)% in urban. While the rate of positive sample was higher 233 (39%) in rural area. The majority of positive samples in this study 119(31.6) were under the 5 years. While the lost positive samples were 44(11.7) mad up the 46 years old. Male members were affected more than the female, where are the infection percent in male was 200(53.1) while in female 176 (46.8). The rate of positive samples was 143(23.9)% in urban. While the rate of positive sample was higher 233 (39%) in rural area.

Conclusion: The result of this study concluded that most of the causative agents of diarrhea in the subjected patients in Al- Sweara hospital and to health centers in Al- Sweara city are of parasitical origin, where Entamoebahistolytica ranks first followed by Giardia lambilae and Escherichia'classical public health approach for infectious diseases must be adopted to control and prevent these diseases. 

Recommendations: For future studies, we recommend further investigations such as: prevalence of various serotypes, electropherotypes and genomic analysis of enteropathogens and ELISA methods for all patients with diarrhea to identify the causative agent involved.

Key Words: diarrhea, enteropathogen, Entamoebahistolytica, mortality, rural.
Diarrhea is a medical condition characterized by inflammation of the gastrointestinal tract and can have many causes, which may be infectious or non-infectious. Infectious diarrheal diseases are a great problem throughout the world and are responsible for considerable morbidity and mortality, especially in developing countries \(^{(1)}\). Infectious diarrhea also remains an important problem in industrialized countries, but the course of the disease is generally mild, and mortality has decreased tremendously over time \(^{(2)}\).

Knowledge of the etiology of diarrhea is important for epidemiological surveillance but also, in many cases, for correct treatment, however recently one of the major challenges in the infectious diarrhea is the recent increase in the number of probable etiological agents \(^{(3)}\), in addition to the main etiology of the diarrhea which related to a wide range of bacteria (such as, Shigella spp., Salmonella spp., E. coli and Vibrio cholera etc.) enteroparasites (Giardia spp. and Entamoebahistolytica etc.), and viruses (Rotavirus, Adenovirus and Norwalk virus etc.) \(^{(1, 4)}\). Also there are some factors that increase an individual's susceptibility to acquired infectious diarrhea which probably include poor personal and food hygiene, lack of clean drinking water \(^{(5)}\). WHO predicts that there will be about 5 million deaths in children younger than five years by 2025, of which 97% will be in the developing countries and mostly caused by infectious diseases, within which diarrhea will continue to play a prominent role \(^{(6)}\).

**Objective:** The frequency of bacterial, parasitic and fungal enteropathogens among 596 children and adults patients who attended Al-Sweara hospital and to health centers in Al-Sweara city were investigated. And the possibility of the influence of some factors such as residence, Sex and Age on the incidence variation of diarrhea and the diversity of its microbial etiology.

**MATERIAL AND METHODS:**

**Time and location (data collection).**

The present study was achieved on (596) children and adult including (371) males and (225) females and they were attended to Al-Sweara hospital and to health centers in Al-Sweara city between the beginning of November 2013 to the end of September 2014 for detection of the microbial causative agents of diarrhea then informative questionnaire form was fill for each patient which include data such as age, sex, residence (urban, rural).

**Collection of stool samples:**

The stool specimens were collected in sterile wide necked containers labeled with names of patients and brought to the laboratory for macroscopic and microscopic examination. All samples were subjected to several diagnostic laboratory tests for detection of bacterial, parasitic and fungal agents.

**Laboratory methods:**

A macroscopic examination was done upon receiving the sample. The fresh stool samples were examined under the microscope using the saline solution by adding a small quantity of the selected fresh stool to one or two drops of normal saline (0.9% NaCl) on the slide with an applicator stick and covered with a cover slip \(^{(8)}\). For trophozoites, ova, cysts etc.

A portion of stool sample was aseptically transferred to a sterile selective enrichment broth to study the incidence of bacterial enteric pathogens present in the diarrheal stool samples. Further, the enriched culture was transferred to selective agar medium for the isolation of different bacterial genera. Starch ampicillin agar (SAA), Eosine methylene blue agar, Brilliant green agar (BGA), Salmonella Shigellaagar (SS), Cetrimide agar, Nutrient agar and Mannitol salt agar (MSA) were used for the selective isolation of different kind of bacteria. The biochemical identification was performed by oxidase reaction, fermentation of sugars, and presence of lysine, gelatine liquefaction, arginine decarboxylation and absence of ornithine decarboxylase, proposed by the method outlined by \(^{(9)}\).

Initially lactophenol cotton blue stain identification and scoring for yeast was made with each fecal sample. Yeast overgrowth was defined as growth of 10⁵ or more colonies\ routine inoculation was done in to look for the growth of a sufficient number of colonies. Culturing
on Sabourauds dextrose agar and corn meal agar for the isolation of the organism was performed by the standard technique.

The identification of yeast was based on a morphological criteria that were included cultural characteristic (shape, size, texture, etc), asexual structure (shape, size, budding pattern, presence\absence of arthroconidia, ballistoconidia, germ tubes, hyphae or pseudo hyphae formation) and on the biochemical and physiological characteristic that were used in identification included assimilation and fermentation of sugars, nitrogen utilization, urea hydrolysis, cyclohexamide resistance and temperature studies\(^{(10)}\).

**Statistical analysis:-**

The results were statistically analyzed by calculating the Chi secure, frequency, percent and p value, and distributed according to age, residence and gender differences using SPSS, version 13.0. P values less than 0.05 was considered significant.

**RESULTS:**

Table 1:- prevalence rat of isolated enteropathogen that are associated with diarrhea.

</table>

This table shows that a higher percentage of diarrhea cases in rural area 167(63.3%) in compression with that of urban area 97(36.7%). Also shows that the percent of diarrheal cases among female was higher (19.4%) than male from urban area which give contrast result with rural area were infected male (34.5) more than infected female (27.3%). but this differences was not statistically significant (p value = 0.5 level).

This table shows that the children with age group < 5 years more susceptible to acquired infectious diarrhea 119(31.6%) followed by the individual with age > 46, while the lowest percentage appear to be in the age group 26-35 were represent 30(7.9%). Also result reveal that males with age group < 5 years represent a high percentage of infection (17.8%) when compared to female (13.8%) at the same ages, which also similar to the deference's between males and females at the age group (26-35)( 5.3%, 2.6% ) respectively. This difference was statistically not significant (p value = 0.5).

**DISCUSSION:**

Infectious diarrhoea are the most important cause of morbidity and mortality in developing countries. The prevalence rate of etiological agent of diarrhea in this study defer in comparison with other parts of Iraq such as Tikrit by Alrifai et al. (2009) who reported that the rate of bacteria was higher (67.9%) than parasitic (11.1%) and fungal represent (2.5%). Our prevalence rate of etiological agent of diarrhea was in agreement with study of Prakash, (2008) in Omman who reported that parasitic isolation rate (18%) was higher than bacterial isolation rate (11.4%). A prevalence of (38.8%) bacterial pathogen isolation from stool cultures fits in the wide range of bacterial pathogen prevalence of 4.8-45%. Our results shows that E. coli was the most prevalence bacterial isolates 13.03% followed by Salmonella Spp. 10.1% and Shigella Spp. 9.5% which was in agreement with other study whose reported that 59.3% were identified as E. coli, (7.4%) were Salmonelliaspecies, while (9%) were Shegilla species. These result may be due to lack of supervision, poor infection prevention practices, Lack of good hygienic conditions, Lack of proper treatment of sanitation level and lack of preventive health system as well as on the presence of insects that help to spread opportunical microbial infections.

The sex distribution among the examined patients in our study showed a slight preponderance of diarrhea in males 53.1% compared with females 46.8%, similar finding have been reported by Johargyet et al. (2010) who found that the prevalence in male 58% higher than females 42%. Also our result was in agreement with other studies in the world for instance, in a study in Nepal Sherchand et al. (2009) reported that the Higher prevalence of diarrhea in male 56.4%, in Missouri Klein, E.J. et al., 2006) was 57% for male and in Tanzania Moyo (2011) 61.4%. This was due to the fact that males are more prone to infection through their presence in places an exposure to contaminated environmental pollution unlike females spend most of their time inside the house and thus the chance of exposure to pollution is lowest.

Different studies have shown that diarrheal infection was more prevalent in children below 5 years of age than other age groups. For instance Bissoumeet et al.,2013) how reported that the higher incidence of infection was among children under 5 years old (50.2%) in agreement with our study. While other study report that the children less than 5 years had a lower rate of infection (19%) which contrast with our study. The increased incidence in this age is most likely because of the large numbers and crowding of kindergartens, as well as the absence of health awareness and the quality of the food used in these places, making them more exposure to enteropathogens plus the immaturity of the immune system of the new born and the decline in passive immunity after age 6 months.

**CONCLUSIONS:**

Our study concluded that most of the causative agents of diarrhea in the subjected patients in Al- Sweara hospital and to health centers in Al- Sweara city are of parasitical origin, where Entamoebahistolytica ranks first followed by Giardia lambilaand. Escherichia.coli, Salmonella Spp. and Shigella Spp. represented the bacterial etiology and Candidaalbicans was the fungal cause. Also the patients with age group less than 5 years old
were more exposed to infect with infectious diarrhea regarding the gender of patients which doesn't represent an ideal factor for increase the infection.

RECOMMENDATIONS:

1- Further investigations such as: prevalence of various serotypes, electropherotypes and genomic analysis of enteropathogens, and ELISA methods for all patients with diarrhea to identify the causative agent involved.

2- The necessity of activating the program of primary health care in rural areas to increase awareness of the health of the people and thus avoid the spread of diarrheal disease and other morbidity epidemic in children and adults as well as to improve more effective methods to sterilize drinking water and the disposal of stray animals and rancid water pools which serve as incubators for insects and pathogenic microorganisms
