ABSTRACT
Numerical Analysis of Unsteady Natural convection in square cavity filled with a porous media studied in this paper. The left vertical wall preserves the constant high temperature Th , and the right wall preserves the constant low temperature Tc and both the horizontal walls are insulated . The alternating –direction implicit method (A.D.I) is used to solve the non-dimensional governing equations, and finite differences method devoted to Nussele numbers and the horizontal and vertical velocity flow . The results are obtained for the initial transient start up to the steady state, and for Rayleigh number($10^2 < Ra < 10^4$). It is observed that the results for average Nusselt number showing an undershoot during the transient period and that the time required to reach the steady state is longer for low Rayleigh number and shorter for high Rayleigh number.

Keywords: Natural Convection, Porous, Square Cavity.

التحليل العددي لانتقال الحرارة بالحمل الطبيعي غير المستقر في تجويف مربع مملوء بوسط مسامي

الخلاصة :

تم دراسة التحليل العددي لانتقال الحرارة بالحمل الطبيعي غير المستقر في تجويف مربع مملوء بوسط مسامي في هذا البحث . الجدار العمودي الأيسر يحتفظ بدرجة حرارة عالية ثابتة T_h والجدار العمودي الأيمن يحتفظ بدرجة حرارة منخفضة ثابتة T_c وكل من الجدارين الأفقيين معزولين عزلا تاما . استخدمت طريقة الاتجاه الضمني المتناوب (A.D.I) لحل المعادلات الحاكمة ، واستخدم طريقة الفروق المحددة لحساب عدد نسلت والسرعة الأفقية والعمودية للجريان . ان النتائج المكتسبة للانتقال الحراري من الحالة الابتدائية إلى حالة الاستقرار ولعدد رالي ($10^2 < Ra < 10^4$) . وقد لوحظ إن معدل عدد نسلت يبين من خلال الفترة العابرة والذي يتطلب وقت للوصول الى حالة الاستقرار أطول عند قيمة عدد رالي قليلة وأقصر عندما تكون قيمة عدد رالي كبيرة .

INTRODUCTION

Convective heat transfer in fluid-saturated porous media has received considerable attention over the last several decades. This interest was estimated due to many applications in, for example, packed sphere beds, high performance insulation for buildings, chemical catalytic reactors, grain storage and such geophysical problems as frost heave. Porous media are also of interest in relation to the underground spread of pollutants, solar power collectors, and to geothermal energy systems. Literature concerning convective flow in porous media is abundant. Representative studies in this area may be found in the recent books by Ingham and Pop [1], Nield and Bejan [2], Vafai [3], Pop and Ingham [4], and Bejan and Kraus [5].

Free convection in a cavity filled with a fluid-saturated porous medium is of prime importance in many technological applications. Examples are post-accident heat removal in nuclear reactors and geophysical problems associated with the underground storage of nuclear waste, among others. The problem of free convection in a rectangular porous cavity whose four walls are maintained at different temperatures or heat fluxes is one of the classical problems in porous media, which has been extensively studied. Much research work, both theoretical and experimental, has been done on this type of convective heat transfer processes. A good deal of references on this problem has been presented in the paper by Lauriat and Prasad [6], and in the recent paper by Baytas and Pop [7]. The model commonly used consists of a porous cavity with both the vertical walls maintained at constant temperatures, while the horizontal walls are adiabatic. The flow and heat transfer characteristics of the steady-state flow is generally studied for this type of cavity. However, a very little work has been done for the case of unsteady and transient flow situations. The aim of this paper is to study numerically the problem of transient free convection in a square cavity filled with a porous medium when one of its vertical wall is suddenly heated and the other wall is suddenly cooled, while the horizontal walls are adiabatic. To our best knowledge, only Banu et al. [8] have presented a study of such a problem, but for a heat-generating porous cavity with all four walls maintained at a constant temperature.

GOVERNING EQUATIONS

A schematic diagram of a two-dimensional square cavity is shown in Fig. (1). It is assumed that the left vertical wall of the cavity heated to the constant temperature T_h and the right vertical wall cooled to the constant temperature T_c, where $T_h > T_c$, and the horizontal walls are adiabatic.

In the porous medium, Darcy's law is assumed to hold, and the fluid is assumed to be a normal Boussinesq fluid. The viscous drag and inertia terms in the governing equations are neglected, which are valid assumptions for low Darcy and particle Reynolds numbers. With these assumptions, the continuity, Darcy and energy equations for unsteady, two-dimensional flow in an isotropic and homogeneous porous medium are :

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \tag{1}$$

$$\frac{\partial u}{\partial y} - \frac{\partial v}{\partial x} = -\frac{g\beta K}{\upsilon}\frac{\partial T}{\partial x} \tag{2}$$

$$\sigma\frac{\partial T}{\partial t} + u\frac{\partial T}{\partial x} + v\frac{\partial T}{\partial y} = \alpha\left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}\right) \tag{3}$$

where u, v are the velocity components along x- and y- axes, T is the fluid temperature and the physical meaning of the other quantities are mentioned in the Nomenclature.
The equations from (1) to (3) can be written in terms of the stream function ψ defined as $u = \partial\psi/\partial y$ and $v = -\partial\psi/\partial x$ together with the following non-dimensional variables:

$$X = \frac{x}{L}, \qquad Y = \frac{y}{L}, \qquad \hat{\psi} = \frac{\psi}{\alpha}, \qquad \theta = \frac{T - T_o}{T_h - T_c}, \qquad \tau = \frac{\alpha t}{\sigma L^2} \tag{4}$$

where $T_o = (T_h + T_c)/2$

The non-dimensional forms of the governing Equations are:

$$\frac{\partial^2 \hat{\psi}}{\partial X^2} + \frac{\partial^2 \hat{\psi}}{\partial Y^2} = -Ra \cdot \frac{\partial \theta}{\partial X} \tag{5}$$

$$\frac{\partial \theta}{\partial \tau} + \frac{\partial \hat{\psi}}{\partial Y} \cdot \frac{\partial \theta}{\partial X} - \frac{\partial \hat{\psi}}{\partial X} \cdot \frac{\partial \theta}{\partial Y} = \frac{\partial^2 \theta}{\partial X^2} + \frac{\partial^2 \theta}{\partial Y^2} \tag{6}$$

where Ra is the Rayleigh number defined as: $Ra = g\beta KL\Delta T / \upsilon\alpha$.
The equations are subjected to the following initial conditions at $\tau = 0$:

$$\hat{\psi} = 0, \qquad \theta = 0, \qquad \text{at any } X, Y \tag{7a}$$

and boundary conditions at $\tau > 0$:

$$\hat{\psi} = 0, \qquad \theta = 0.5, \qquad \text{at } X = 0, \qquad \text{any } Y \tag{7b}$$

$$\hat{\psi} = 0, \qquad \theta = -0.5, \qquad \text{at } X = 1, \qquad \text{any } Y \tag{7c}$$

$$\hat{\psi} = 0, \qquad \partial\theta/\partial Y = 0 \qquad \text{at } Y = 0,1 \qquad \text{any } X \tag{7d}$$

NUMERICAL METHOD
By using the Alternating-Direction Implicit method (A.D.I) in this paper to solve the governing equations (eq. (5) and eq. (6)) , at any increase in the time, doing in two stage of time. Then the eq. (5) written as :

At first stage :

$$\frac{\hat{\psi}^{l+1/2}_{i+1,j} - 2\hat{\psi}^{l+1/2}_{i,j} + \hat{\psi}^{l+1/2}_{i-1,j}}{(\Delta X)^2} + \frac{\hat{\psi}^{l+1/2}_{i,j+1} - 2\hat{\psi}^{l+1/2}_{i,j} + \hat{\psi}^{l+1/2}_{i,j-1}}{(\Delta Y)^2} = -Ra \cdot \frac{\theta^{l}_{i+1,j} - \theta^{l}_{i-1,j}}{2\Delta X} \tag{8}$$

At second stage :

$$\frac{\hat{\psi}_{i+1,j}^{l+1} - 2\hat{\psi}_{i,j}^{l+1} + \hat{\psi}_{i-1,j}^{l+1}}{(\Delta X)^2} + \frac{\hat{\psi}_{i,j+1}^{l+1} - 2\hat{\psi}_{i,j}^{l+1} + \hat{\psi}_{i,j-1}^{l+1}}{(\Delta Y)^2} = -Ra \cdot \frac{\theta_{i+1,j}^{l+1} - \theta_{i-1,j}^{l+1}}{2\Delta X} \tag{9}$$

And the eq. (6) written as :
At first stage :

$$\frac{\theta_{i,j}^{l+1/2} - \theta_{i,j}^{l}}{2\Delta\tau} + \frac{\hat{\psi}_{i,j+1}^{l+1/2} - \hat{\psi}_{i,j-1}^{l+1/2}}{2\Delta Y} \cdot \frac{\theta_{i+1,j}^{l} - \theta_{i-1,j}^{l}}{2\Delta X} - \frac{\hat{\psi}_{i+1,j}^{l+1/2} - \hat{\psi}_{i-1,j}^{l+1/2}}{2\Delta X} \cdot \frac{\theta_{i,j+1}^{l+1/2} - \theta_{i,j-1}^{l+1/2}}{2\Delta Y} =$$

$$\frac{\theta_{i+1,j}^{l} - 2\theta_{i,j}^{l} + \theta_{i-1,j}^{l}}{(\Delta X)^2} + \frac{\theta_{i,j+1}^{l+1/2} - 2\theta_{i,j}^{l+1/2} + \theta_{i,j-1}^{l+1/2}}{(\Delta Y)^2} \tag{10}$$

At second stage :

$$\frac{\theta_{i,j}^{l+1} - \theta_{i,j}^{l+1/2}}{2\Delta\tau} + \frac{\hat{\psi}_{i,j+1}^{l+1} - \hat{\psi}_{i,j-1}^{l+1}}{2\Delta Y} \cdot \frac{\theta_{i+1,j}^{l+1} - \theta_{i-1,j}^{l+1}}{2\Delta X} - \frac{\hat{\psi}_{i+1,j}^{l+1} - \hat{\psi}_{i-1,j}^{l+1}}{2\Delta X} \cdot \frac{\theta_{i,j+1}^{l+1/2} - \theta_{i,j-1}^{l+1/2}}{2\Delta Y} =$$

$$\frac{\theta_{i+1,j}^{l+1} - 2\theta_{i,j}^{l+1} + \theta_{i-1,j}^{l+1}}{(\Delta X)^2} + \frac{\theta_{i,j+1}^{l+1/2} - 2\theta_{i,j}^{l+1/2} + \theta_{i,j-1}^{l+1/2}}{(\Delta Y)^2} \tag{11}$$

The initial conditions are very effect in this problem, we should take that in this study. A.D.I method solved this problem in two stages , therefore the initial conditions in two stages , in the first stage the vertical initial conditions affect greater than the horizontal initial conditions, and in the second stage the horizontal initial conditions affect greater than the vertical initial conditions.
The solution domain consist of grid points at which the discrimination equations are applied. In this domain X and Y , by definition varies from 0 to 1, the uniform grid has been selected in both X and Y directions. The grid size and geometry were tested, and it was found that the following size and geometry give the best results comparing with the results in the literature for the steady-state flow. The grid size is (60*60) and the grid geometry is symmetrical about the centerlines.
The heat transfer should be solved in the near hot left wall and the near cooled right wall by using the (Forward difference & backward difference techniques) from this equations:

$$Q_h = -\int_0^1 \left.\frac{\partial\theta}{\partial X}\right|_{at\,X=0} dY \qquad \text{and } Q_c = -\int_0^1 \left.\frac{\partial\theta}{\partial X}\right|_{at\,X=1} dY \tag{12}$$

RESULTS AND DISCUSSION :
The streamlines and isotherms at different time steps ranging from $\tau = 0.0025$ to $\tau = 0.08$ are shown in Fig. 2 for $Ra = 1000$. It can be seen that early in the transient region, the isotherms are nearly parallel indicating conduction heat transfer and the fluid is rising up near the hot left wall and is fallen downward near the cooled right wall, respectively. A recirculation flow region of small intensity sites close to the upper part of the hot wall or to the lower part of the cooled wall and spin the fluid towards the center of the enclosure (Fig. 2a). Shortly after that, the fluid travels across the upper (or lower) half of the enclosure (Fig. 2b). The streamlines indicate an elongation of the recirculation region of the flow

along with a transition to the middle of the enclosure (Fig. 2b). With increasing of time ($\tau = 0.01$), the majority of fluid is rising up or falling down near the hot wall and near the cooled wall, respectively (Fig. 2c) and the local Nusselt number is continuously decreasing near the upper part of the hot wall (Fig. 3b). Further, after a short time ($\tau = 0.02$), the flow has been extended throughout the cavity and convection has became more important (Fig. 2d). For $\tau > 0.04$ the flow is then going to attain the steady-state regime (Fig. 2e), which happens for $\tau = 0.08$ (Fig. 2f). The streamlines and the isotherms at $\tau = 0.08$ presented in Fig. 2f are almost identical to those given by Baytas and Pop [7], and Baytas [10]. The development of the velocity and thermal boundary layers on the vertical walls of the cavity can be clearly observed from these figures, which continuously grow to the steady-state thermal boundary layers flow. The development of the velocity and thermal boundary layers for $Ra = 10^2$ and $Ra = 10^4$ are similar to those shown in Fig. 2. The difference is that for low Rayleigh number condition the convection currents will be weaker which leads to the grow of the boundary layer will be slower than for high Rayleigh number condition. The stream lines and the isotherms for $Ra = 10^2$ and $Ra = 10^4$ are not shown for brevity.

The variation of the transient local Nusselt number with time τ along the hot wall of the cavity at different positions Y is presented in Fig. 3 for $Ra = 10^2 - 10^4$. It is seen that immediately after the process of impulsively heating starts the value of the local Nusselt number goes to infinity (is singular) and this is characteristic to any impulsively started heating system. Then, at small positions ($Y < 0.5$), the local Nusselt number decreases for a short time followed by a constant value and then increase to reach the steady state value. Fig. 3c shows that this phenomenon will happen for the upper half also ($Y \geq 0.5$) for $Ra = 10^4$. However, for $Y \geq 0.5$ and $Ra = 10^2$ and $Ra = 10^3$ the local Nusselt number decreases continuously with increasing time until it reaches its steady-state value. This variation of the transient local Nusselt number is reflected on the average Nusselt number which is defined in Eq. (10). Fig. 4 shows the variation of the average Nusselt number with the non-dimensional time for different Rayleigh numbers. The average Nusselt number showing an undershoot during the transient period followed by a constant steady state value for all $Ra = 10^2 - 10^4$. It is also observed that the time required to reach the steady state (*Nu* becomes constant) is longer for low Rayleigh number and shorter for high Rayleigh number as shown in Figs. 3 and 4.

Further, values of the average Nusselt number along the hot wall of the cavity at the steady-state flow for $Ra = 10^2 - 10^4$ are given in Table 1. It is seen again that the present values of $\overline{Nu}$ are in very good agreement with that obtained by different authors, such as Walker and Homsy [11], Bejan [12], Gross et al. [13], and Manole and Lage [14]. Therefore, these results provide great confidence to the accuracy of the present numerical model. It is important to recall that the above results were obtained using the thermal equilibrium between the solid and fluid phases in the porous media assuming low Reynolds number and low porosity. The effect of the non-equilibrium is usually considered for higher fluid velocity as well as higher porosity which need further investigation as extension to the present research.

CONCLUSIONS

The transient free convection in a two-dimensional square cavity filled with a porous medium is considered in this paper. The flow is driven by considering the case when one of the cavity vertical walls is suddenly heated and the other vertical wall is suddenly cooled, while the horizontal walls are adiabatic. The non-dimensional forms of the continuity, Darcy and energy equations are solved numerically. The A.D.I. method is used for the convection–diffusion formulation in the uniform grid in both horizontal and vertical directions. It is observed during the transient period that the average Nusselt number showing an undershoot followed by a constant steady state value for all $Ra = 10^2 - 10^4$ and at the steady state the flow and heat transfer characteristics are similar to those from the open literature. It is also observed that the time required to reach the steady state is longer for low Rayleigh number and shorter for high Rayleigh number.
