The Effect of Power System Stabilizers (PSS) on Synchronous Generator Damping and Synchronizing Torques

Asst. Lecturer Fadhil M. Kalaf*

ABSTRACT

The synchronizing and damping torque coefficients in the range of the electromechanical oscillation frequencies provide a measure of the generators' contribution towards power system stability under small deviations, and may be taken as stability indices even for multi machine systems, although their interpretation is rather complex in this case. This paper presents the effect of Power System Stabilizer (PSS) on the synchronizing and damping torque coefficients for a synchronous generator connected to an infinite busbar through impedance; it explicitly includes the effects of its Automatic Voltage Regulator (AVR) and of the additional stabilizer signal derived from the rotor speed.

Results obtained were compared with the conventional (AVR) using MATLAB 7 programming language.

Keywords: Power System Stabilizer, AVR, synchronizing torque, damping torque

* Technical College
INTRODUCTION

A traditional function of the excitation system is to regulate generator voltage and thereby help control system voltage. The power system stabilizer (PSS) is a supplementary controller, which is often applied as part of the excitation control system. Grid codes and regulatory agencies are increasingly specifying PSS controls for new generation and retrofit on existing units. The basic function of the PSS is to apply a signal to the excitation system, creating electrical torques that damp out power oscillations.

Although the primary function of the PSS is to supply positive damping torque contributions, experience indicates that it can impact the generator-power system transient performance under certain conditions.

Dynamic instability is related to the high loading of modern electrical power systems, to the design of lower-cost synchronous generators and especially to the use of high-gain and quick-acting excitation systems. To improve the damping of electromechanical oscillations when necessary, such systems should be designed to allow proper processing of stabilization signals, usually derived from the machine rotor-speed or electrical power. [1]

J.H.Chow and J.J.Sanchez-Gasca [2] examine the four pole-placement for the design of the power system stabilizer with the emphasis on the frequency characteristics of these controllers.

M. A. Abido and Y. L. Abdel-Magid [3] proposed a robust design of multi-machine Power System Stabilizers (PSS) using Tabu Search (TS) optimization technique. The eigenvalues analysis and the nonlinear simulation results show the effectiveness of the proposed PSS to damp out the local as well as the interarea modes and enhance greatly the system stability over a wide range of loading conditions and system configurations.

K. Hongesombut, and Y. Mitani [4] focuses on the use of advanced techniques in genetic algorithm for solving power system stabilization control problems. These advanced techniques provide enhanced versatility for solving problems in power system stabilization control.

K.T.Law et.al[5] exploited the internal model (IMC) technique to analyze the inherent conflict between voltage regulation and damping improvement for synchronous generators.
Payman Shamsollahi [6] described an adaptive power system stabilizer using on-line trained neural networks which is tested on a single-machine infinite-bus power system model for a variety of disturbances.

C.X.Mao [7] described an adaptive optimal control algorithm for two real time control applications for synchronous generator and power system stabilizer.

2. PLANT MODEL

To investigate the effectiveness of using the power system stabilizer (PSS) with the automatic voltage regulator (AVR), the plant model which is the exciter-generator is shown in Figure 1 below. A mathematical model for the exciter-generator plant was derived depending on the Swing Equation viewpoint. The equation of central importance in power system stability analysis are the rotational inertia equation describing the effect of unbalance between the electromagnetic torque and the mechanical torque of the individual machines.

The normalized swing equation then can be expressed as two first order differential equations, then

$$\frac{d(\Delta \omega_r)}{dt} = \frac{1}{2H} (\overline{T_m} - \overline{T_e} - K_D \Delta \omega_r)$$

(1)

$$\frac{d\delta}{dt} = \omega_0 \Delta \omega_r$$

(2)

The plant model will be introduced in the form of state space vector differential equation $\dot{x} = Ax + Bu$. [8, 9, 10, 11]
The $V_{ref}$ and $\Delta P_m$ will be taken as inputs to the plant then,

$$
\frac{d}{dt} \begin{bmatrix}
\Delta \omega_r \\
\Delta \delta \\
\Delta E' \\
\Delta E_{jd}
\end{bmatrix} = \begin{bmatrix}
-K_D & -K_1 & -K_2 & 0 \\
2H/\omega_o & 2H & 2H & 0 \\
0 & -K_3K_4 & -1 & K_3 \\
0 & -KAK_5 & 0 & -K_E/T_E
\end{bmatrix} \begin{bmatrix}
\Delta \omega_r \\
\Delta \delta \\
\Delta E' \\
\Delta E_{jd}
\end{bmatrix} + \begin{bmatrix}
1 & 0 \\
0 & 2H/\omega_o \\
0 & 0 & K_A \omega_o/T_E
\end{bmatrix} \begin{bmatrix}
\Delta P_m \\
V_{ref}
\end{bmatrix}
$$

(3)

Then from equation (3)
3. PERFORMANCE EVALUATION of DESIGNED CONVENTIONAL AVR

For the conventional AVR the output in the state-space can be taken arbitrary, for the model of equation (3), the terminal voltage \( \Delta E_t \) is taken to be an output and can be given as:

\[
\Delta E_t = K_5 \Delta \delta + K_6 \Delta E' + \Delta E''
\]  
(4)

or in a matrix form

\[
\begin{bmatrix}
\Delta \omega_r \\
\Delta \delta \\
\Delta E' \\
\Delta E_{fd}
\end{bmatrix}
= [0 \quad K_5 \quad K_6 \quad 0]
\]

(5)
The synchronizing torque and the damping torque coefficients can be calculated from the equations

\[ \omega_n = \sqrt{K_S \frac{\omega_n}{2H}} \text{ rad/s} \]

(6)

And the damping ratio is

\[ \zeta = \frac{1}{2} \frac{K_D}{2H\omega_n} \]

\[ = \frac{1}{2} \frac{K_D}{\sqrt{K_S^2 2H\omega_n}} \]

(7)

By changing the value of KA from 1 to 90 (the gain 90 is the maximum that after this value the instability will be reached). Then for these changes evaluating the values of the \( K_S \), \( K_D \) (as given in equations 5 and 6), and the time domain specifications is evaluated are shown in Table 1. Figures 2 and 3 displays the plots of the output terminal voltage \( E_t \) versus t for number of KA values.

(Note: if \( V_{ref} \) is taken to be zero p.u, then the output will be the rate of change of the terminal voltage \( \Delta E_t \), else if \( V_{ref} \) is taken to be 1p.u then the output will be the terminal voltage \( E_t \), which is the case in this paper).

4. PERFORMANCE EVALUATION of THE DESIGNED CONVENTIONAL AVR AND PSS

The basic function of the power system stabilizer (PSS) is to add damping to the generator rotor oscillations by controlling its excitation using auxiliary stabilizing signal(s). To provide damping, the stabilizer must produce a component of electrical torque in phase with the rotor speed deviations.

The basis for a PSS may be illustrated with the aid of the block diagram shown in Figure 4. This is an extension of the block diagram of Figure 1 and includes the effect of PSS.

Since the purpose of a PSS is to introduce a damping torque component, a logical signal to use for controlling generator excitation is the speed deviation.
The PSS transfer function, should have appropriate phase lead compensation circuits to compensate for the phase lag between the exciter input and the electrical torque.

If the phase-lead network provides more compensation than the phase lag between \( \Delta T_e \) and \( \Delta V_s \), the PSS introduces, in addition to a damping component of a torque a negative synchronizing torque component. Conversely, under compensation a positive synchronizing torque is introduced.

The PSS representation in Figure 5 consists of three blocks: a phase compensation block, a signal washout block, and a gain block.

System state matrix including PSS is shown below

Figure 5 Block diagram showing the PSS
The terminal voltage $\Delta E_t$ is taken to be an output and can be given as in equation (4) or in state-space representation

\[
\begin{bmatrix}
\Delta \omega_r \\
\Delta \delta \\
\Delta E \\
\Delta E_{fd}
\end{bmatrix} =
\begin{bmatrix}
\frac{-K_D}{2H} & \frac{-K_3}{2H} & \frac{-K_2}{2H} & 0 & 0 & 0 \\
0 & \frac{-K_3K_4}{T_3} & \frac{-1}{T_3} & \frac{K_3}{T_3} & 0 & 0 \\

(8)

By changing the value of $KA$ from 1 to 90. Then for these changes evaluating the values of the $K_S$, $K_D$ and the time domain
specifications, as given in Table 2. Figures 6 and 7 displays the plots of the output terminal voltage $E_i$ versus $t$ for number of $KA$ values in the presence of PSS. From these figures, it can be shown how the damping torque coefficient ($K_D$) increases and with respect to the damping torque coefficient evaluated in Table 1.

5. CONCLUSIONS

In this paper at first the conventional AVR was adopted to the synchronous generator whose data are given in Appendix A. The synchronizing torque coefficient and the damping torque coefficient are given in Table 1 and the time domain responses are displayed in Figures 2 and 3. Then the conventional AVR with the power system stabilizer (PSS) was adopted to the same synchronous generator. The synchronizing torque coefficient and the damping torque coefficient are given in Table 2 and the time domain responses are displayed in Figures 6 and 7.

From the evaluated Tables and the time domain plots it is shown that the damping is low, and if the gain of the regulator is increased then the damping will be less. In order to solve this problem and to increase damping, the Power System Stabilizer (PSS) was used. Then $K_D$ was increased after using the PSS from 0.1033 to 0.7112 for a gain $KA = 90$, also the settling time was enhanced and decreased from 504 sec to 73.8 sec and the same thing is true for the other gains. It is clear that the synchronizing torque does not so effected by the PSS as shown in Tables 1 and 2.
