Hepatoprotective and some haematological parameters effect of *Allium ampeloprasum* against carbon tetrachloride induced liver toxicity in albino rats

Afyaa sabah nasir

Faculty of Science, Kufa University

Abstract:

The aim of the present study is to prepare ethanol extract of leek and to study the effect of its on body weight, liver weight, serum liver function enzymes, serum lipids profile and in carbon tetrachloride (CCL4) intoxicated rats. Used thirty six male rats were divided into 6 equal groups. One group of rats was fed on basal diet and kept as a negative control while three groups were administrated by CCL4 at a dose of 0.5 ml/kg body weight for induction of acute liver toxicity. The first group of the intoxicated rats was left as a positive control while the others were fed on experimental diets with leek extract at 200,400 mg/kg and other two groups were gives only 200,400 mg/kg of leek extract. At the end of experimental period (4 weeks), the rats were sacrificed and blood samples were collected for biochemical analyses. Livers of the sacrificed rats were removed and prepared for histopathological examination. Results showed that treatment effect of leek extract especially at 400 mg/kg in CCL4-intoxicated rats improved their body weight. Also decreased the levels of liver enzymes,total cholesterol,triglycerides and improved lipid profile. While the doses 200,400 mg/kg of leek extract groups appear normal values of all parameters in this study. Finally histopathological examination revealed alleviation of hepatic lesions caused by CCL4 by increasing the concentration of leek extract used. In conclusion, it was suggested that leek extract could protect the liver cells from CCL4-induced liver damages perhaps, by its antioxidative effect on hepatocytes, hence eliminating the deleterious effects of toxic from CCL4.

Key words: *Allium*, Body weight, Liver weight, Liver enzymes, lipoprotein, Histopathology, CCL4 and Rats.
Introduction:

The liver is the most important organ in the body. It plays a pivotal role in regulating various physiological processes. It is also involved in several vital functions, such as metabolism, secretion and storage. It has great capacity to detoxicate toxic substances and synthesize useful principles (1,2). It helps in the maintenance, performance and regulating homeostasis of the body. It is involved with almost all the biochemical pathways to growth, fight against disease, nutrient supply, energy provision and reproduction. In addition, it aids metabolism of carbohydrate, protein and fat, detoxification, secretion of bile and storage of vitamins (3). The role played by this organ in the removal of substances from the portal circulation makes it susceptible to first and persistent attack by offending foreign compounds, culminating in liver dysfunction (4).

Liver diseases remain one of the major threats to public health and are a worldwide problem (5). They are mainly caused by chemicals like acetaminophen (in large doses), excess consumption of alcohol, infections and autoimmune disorders. Most of the hepatotoxic chemicals damage liver cells mainly by inducing lipid peroxidation and other oxidative damages (6,7,8).

Medicinal plants play a key role in human health care. About 80% of the world population relies on the use of traditional medicine, which is predominantly based on plant material (9). The allium group is one of the world’s most widely cultivated vegetable groups, with their culinary and medicinal uses. Equally varied are their health benefits, for they contain a range of phytochemicals with an array of biological effects. Evidence shows they play an important role in protecting against major lifestyle chronic diseases as well as health problems associated with ageing. Their antimicrobial activity, long recognized in folk remedies, has also now been scientifically validated (10,11).

The Allium genus includes approximately 500 species, the most widely used of which are onions, garlic, shallots, chives, scallions and leeks (12). Leeks (Allium porrum or A. ampeloprasum var. porrum), sometimes called "the gourmet's onion" have flat leaves instead of tubular and relatively little bulb development and is native to Western Asia and the Mediterranean countries. The thick leaf bases and slightly developed bulb look like a giant green onion, and are eaten as a cooked vegetable. Leeks contain saponins and the major flavonoid in leeks is kaempferol, with only a small amount of quercetin, carotenoids and chlorophyll mainly in the green tops (13,14).
Materials and methods:

Materials:

Chemicals: Carbon tetrachloride (CCL4) were obtained from the chemistry department/kufa university. The rats received a dose of (0.5) ml/kg of CCL4 was suspended in olive oil (1:1v/v) by interagastric intubation method as well as leek extract was given at a dose 200 mg/kg, 400 mg/kg by interagastric intubation method also.

Leek leaves: were obtained from the local market in al Najaf city, Iraq.

Methods:

Preparation of leek extract: The leek leaves were dried at (45°C) and crushed to powder by using a blender, take a bout 100g of powdered were added to 500ml of 80% ethanol and put the mixture in soxhelt system during 24h. After that, resulting extracts were filtered using filter paper and concentrated to dryness in rotary evaporator in the room temperature and the recipient was used by several dilution (15).

Experimental Design: Thirty six male albino rats strain (Rattus rattus) weighting (230-250g) obtained from the animal house in the science faculty / Kufa university, Najaf. The rats kept under observation for one week before starting the experiment for acclimatization. Fed on standard diet and water ad libitum. Then animals were divided into six groups of six rats in each. The first group was fed on the basal diet and served as a negative control (-Ve). The three groups were given carbon tetrachloride (CCL4) for induction of acute liver damage. CCL4 was diluted in an equal volume of olive oil as a vehicle and interagastric intubation method in a dose of 0.5 ml/kg body weight (16). The first hepatotoxic group was fed basal diet and kept as a positive control (+Ve) while the other hepatotoxic groups were fed on basal diets that substitute 200,400 mg/kg of leek extract. The rest two groups were fed on basal diets that substitute 200 and 400 mg/kg of leek extract only.

At the end of experiment period (4 weeks), rats were anaesthetized by ether and blood samples were collected from the portal vein divided in two parts the one put into dry centrifuge tubes and were centrifuged for 20 minutes at 3000 rpm and other parts put in EDTA tube for haematological analyses (Hb, PCV). After separate the sera which were kept at 10°C till biochemical analysis. Livers of the sacrificed rats were removed for histopathological examination.

Biochemical Analyses: The collected serum samples were used for estimating aspartate amino transferases (AST), alanine amino transferases (ALT) (17), and alkaline phosphatase enzymes (ALP) (18). Serum total cholesterol (TC) (19), triglycerides (TG) (20) and high density lipoprotein (HDL) (21) were determined calorimetrically. Low density lipoprotein cholesterol (LDL) and very low density lipoprotein cholesterol (VLDL) were calculated mathematically according to Friedwald's equations (22).

LDL = TC-[HDL+ (TG/5)]

VLDL = Triglycerides/5.

Histopathological Studies of the Liver: Livers of the scarified rats were dissected, removed, washed with normal saline and put in 10% formalin solution. The fixed specimens were then trimmed, washed and dehydrated in ascending grades of alcohol. The tissue specimens were cleared in xylene, embedded in paraffin, sectioned at 4-6 microns thickness, stained with Hematoxylen and Eosin (H and E) and then studied under an electronic microscope (23).

Statistical Analysis: Results were expressed as means±S.E. Statistical analysis was carried out using computerized SPSS program (version 17) with one way ANOVA (24).

Results and Discussion:

The liver, the key organ involved in numerous metabolic functions and detoxification of hazardous substances, is
a frequent target of a number of toxicants (25). There is no doubt that reactive oxygen species play an important role in pathological changes in the liver, particularly in the cases of alcoholic and toxic liver diseases (26). It is now generally accepted that the hepatotoxicity of CCl4 is the result of reductive dehalogenation, which is catalyzed by P-450 enzyme system and which forms highly reactive trichloromethyl free radical. This readily interacts with molecular oxygen to form the trichloromethyl peroxy radical. Both trichloromethyl and its peroxy radical are capable of binding to proteins or lipids, or of abstracting a hydrogen atom from an unsaturated lipid, initiating lipid peroxidation and liver damage and by doing so playing a significant role in pathogenesis of diseases (27,28).

In the table (1) showed the body weight significant decrease (p<0.05) as a result of CCl4 administration was considered to be the result of direct toxicity of CCl4 and indirect toxicity related to the liver damage. Changes in the body weight after CCl4 dosing have been used as a valuable index of CCl4-related organ damage (29,30).

CCl4 is one of the chemicals that affect on the liver causing hepatic injury leading to acute inflammation followed by its chronic form, which may be complicated by cirrhosis and hepatocellular carcinoma, all these affects causes significant decrease (p<0.05) in the liver weight (31).

Vegetables are an important source of mineral and phenolics which play an important role in nutritive value. Allium vegetables and related organosulfur compounds inhibit of mutagenesis, modulation of enzyme activities, inhibit of DNA adduct formation, scavenge of free-radical, and effect on cell proliferation and tumor growth (32). Leeks are a good source of dietary fiber, folic acid and calcium. Leeks are easy to digest and have laxative, antiseptic, diuretic, and anti-arthritic properties (33). Leeks support healthy digestion by promoting the growth of useful bacteria in the gut due to contain prebiotics carbohydrates that serve as fuel for good bacteria in the digestive tract. These probiotic bacteria fortify the immune systems and keep digestive processes running smoothly. Leeks fiber energizes the human body to perform many types of biological functions like digestion, metabolism and growth therefore leeks digest causes significant increase (p<0.05) in the body weight and other organs as liver (34).

Table (2) show in positive control group significant decreased (p<0.05) hemoglobin and packed cell volume compared to negative control group. The treated groups with ethanol extract of leek 200 mg/kg and 400 mg/kg and CCl4 showed non significant decrease (p<0.05) in hemoglobin and packed cell volume compared to negative control group. The treated groups with ethanol extract of leek 200 mg/kg and 400 mg/kg only showed significant increase (p<0.05) in hemoglobin and packed cell volume compared to negative control group, this results were similarity with (35).

Leeks are a good source of allyl sulfides and also rich in the flavonoid especially kaempferol. Leeks contain excellent amounts of vitamin C, as well as folate, and some useful amounts of B vitamins, vitamin E, copper, potassium and iron. These vitamins and minerals work together to help stabilize blood. Calcium in leeks is also used for the proper clotting of blood in the human body in addition of iron was increased the haemopoiesis process in the bone marrow due to significant increased levels (p<0.05) of the hemoglobin and packed cell volume in the blood (36). Allium species also have immune enhancing actions that include promotion of lymphocyte synthesis, cytokine release, phagocytes and natural killer-cell activity.
Assessment of liver function in the table (3) can be made by estimating the activities of serum AST, ALT and ALP which are enzymes originally present higher concentration in cytoplasm. When there is hepatopathy, these enzymes leak into the blood stream in conformity with the extent of liver damage (38). The elevated level of these entire marker enzymes observed in the positive control group corresponded to the extensive liver damage induced by toxin. These results are in agreement with previous finding that the activity levels of serum AST, ALT and ALP were significantly elevated (p<0.05) in rats after CCl4 administration (39). The reduced concentrations of AST, ALT and ALP as a result of leek extract administration, the tendency of these marker enzymes to return towards a near normalcy in ethanol extract of leek administration groups point towards an early improvement in the secretory mechanism of the hepatic cell and is a clear manifestation of anti-hepatotoxic effect of leek extract in CCl4 administration rats. In another study (41) suggested that one reason for the preventive effect of leek against the atherosclerotic process may be the changes in the portions of lipoprotein cholesterol fractions. Moreover, previous studies have shown that ingestion of leek appears to inhibit hepatic fatty acid synthesis by lowering key enzymes activities in supplying substrates, thus reducing lipid accumulation in the liver and TG level in plasma. With respect to the cholesterol lowering property of leek, it has been suggested that some constituents of leek may act as inhibitors for some enzymes such as hydroxyl methyl glutarylCoA reductase, which participates in cholesterol synthesis (42).

Six rats in each groups

Histopathological examination of livers of the negative control rats fed on basal diet revealed normal histological picture of hepatic lobule which consists of central vein surrounded by normal hepatocytes as shown in Fig. (1-A). Examination of liver of the CCL4-intoxicated positive control rats showed severe fatty degeneration of hepatocytes and infiltration of leucocytes in hepatic sinusoid (Fig.1-B). Livers of CCL4-intoxicated rats fed on diet+200mg/kg leek extract showed little vacular degeneration of hepatocytes as shown in Fig. (1-C) while livers of CCl4-intoxicated rats fed on diet+400mg/kg leek extract showed almost normal histology of the hepatic lobule (Fig.1-D). Finally Livers of groups gives only leeks extract showed as negative control rats (Fig.1-E,F).The higher concentration of leek extract the improvement in liver histopathology.

Figure(1) Histopathological changes detected in the liver of (A) control-ve (B) control + ve (C) CCL4+200 mg/kg leek (D) CCL4+400 mg/kg leek (E) 200 mg/kg leek and ( F) 400 mg/kg leek.(40X).
**Conclusion:** From these results, it was suggested that ethanol extract of leek could protect the liver cells from CCl4-induced liver damages perhaps, by its antioxidative effect on hepatocytes, hence eliminating the deleterious effects of toxic metabolites from CCl4. So the present study recommended that the use of the leeks may be useful for patients suffering from liver diseases due to its hepatoprotective and hypolipidemic activities.
