Abstract

Propolis is a natural resinous substance obtained from bee hives living on various plant sources. The present experiment was designed to investigate the protective role of ethanolic extract of local propolis against the possible reproductive harmful effects induced by acrylamide when administered orally in male rats. A total of Thirty sexually mature male albino rats were randomly divided equally into three different groups (n = 10) , the first one : served as normal control , the second group received acrylamide alone (150 mg / Kg BW) , the third group received acrylamide in same dose and treated with local propolis extract (200 mg / Kg BW) twice daily. Doses were given by drenching for four weeks. The result of study revealed that administration of acrylamide induced significant decrease in the sperm concentration, sperm motility, rate of viability and normal sperms as well as decrease in weights of testes, epididymis, prostate gland, seminal vesicles, serum testosterone, FSH, LH levels with significant increase in sperm abnormalities compared with control group. Treatment with local propolis extract improved the harmful effects of acrylamide on reproductive parameters in male rats toward the normal values.

Introduction

Infertility is one of the major health problems in life and approximately about 30% of this problem is due to male factor (1). Acrylamide used in many fields, from industrial manufacturing to laboratory work, is also formed during the heating process through the interactions of amino acids. Therefore, acrylamide poses a significant risk for both human and animal health (2). Acrylamide was shown to be a neurotoxicity (3) reproductive toxicity (4) and carcinogen in animal species (5). Propolis is a resinous substance derived from the plant resins collected by honeybees. Bees use it as a glue, general-purpose scaler, and draught extruder for beehives. Its color varies from green, red to dark brown (6). Etymologically, the Greek word propolis means pro, for or in defence, and polis, the city, that is “defence of the hive”. Bees use it to seal holes in their honeycombs, smooth out internal walls as well as to cover carcasses of intruders who died inside the hive in order to avoid their decomposition. Propolis also protects the colony from diseases because of its antiseptic efficacy and antimicrobial properties (7). Complexity and variety of the chemical composition of propolis has been reported in the literature, From different botanical and geographical origins of world, more than 300 compounds including volatile organic compounds, flavonoid aglycones, phenolic acids and their esters, phenolic aldehydes, alcohols and ketones, sesquiterpenes, quinones, coumarins, steroids, aminoacids were reported to have been isolated from propolis (8,9). Most of the compounds from isolated propolis include the phenolics with important protective effect against oxidation reactions such as those with regular agents like BHT and hydroquinone. Flavones, coumarines, and many other phenolic compounds have reducing activity, hydrogen-donors and metal chelating properties. They are also used as radical quenchers in organic solutions and biological fluids (10,11) They have been used since ancient times as a medicine because of their biological properties as anti-
inflammatory, anti-allergic properties, anti-carcinogenic, anti-oxidative, anti-fungal, anti-viral, immuno-stimulant and for tissue regeneration.(12,13) The use of propolis for various purposes has a long history dating back to at least 300 BC (14) and even now, in the 21st century, it is used in home remedies and personal products (15) Propolis has also gained popularity in various parts of the world, including the United States, Japan, and the European Union, where it is claimed that it improves human health and prevents conditions such as inflammation, heart disease, diabetes and even cancer (16,17) Caffeic acid phenethyl ester (CAPE) is the active component of propolis (18) So the aim of the present study was to evaluate the protective effects of an ethanolic extract of local propolis when administrated orally on the some male reproductive parameters after administration of acrylamide in rats.

Material & methods

- **Propolis samples :**

Propolis samples were collected from local beehives of honey bees in Al-Diwanyia city, Iraq during spring and may in 2011. after that, propolis samples were cleaned, free of wax, paint, wood, cut into small pieces, and kept in the dark at 4 c until use.

- **Ethanolic extract of propolis :**

Twenty gram of crude propolis were mixed with 100 ml of ethanol alcohol (70%) in dark brown bottle for extraction . The mixture was left for 7 days at room temperature and in dark place. the container was shaked 2 or 3 times per day and returned to warm dark place. The mixture was filtered through Whatman No. 1 filter paper. This process was repeated twice. Finally the alcohol was evaporated by oven at 45°C, then the extract was weighed and stored in dark clean container until use.

Animal design:

- **Animals**

Healthy adult male albino rats of the Wistar strain with proven fertility, 5–6 months of age and weighing 200–250 g, were supplied from the Animal Breeding House of the Medical college in Al-najaf University, Al-Najaf, Iraq. Animals were housed in plastic cages with standard dimension under controlled temperature (23 ± 2 °C), 12-h light/dark cycle and 60 relative humidity. Water and food were available ad labium. Rats were acclimatized to the laboratory environment for two weeks prior to the start of experiments.

- **Experimental design**

After the period of acclimation, animals were divided into three equal groups with 10 animals in each group. The first group was used as negative control . The second male group was orally treated with acrylamide (150 mg/kg B.W) . The third male group was orally treated with propolis (200 mg/kg b.w.) twice daily after administration of acrylamide substance orally in the same dose (150 mg/kg B.W) The duration of the oral administration during the experiments lasts for 30 day.

- **Semen characteristics:**

Semenal content of epididymis was obtained by cutting of cuda epididymis using surgical blades and squeezed in a sterile clean watch glass. This content was diluted 10 times with 2.9 % sodium citrate dehydrate solution and thoroughly mixed to estimate the progressive motility and sperm concentration (19). One drop of the suspension was smeared on a glass slide and stained by Eosin-nigrosin stain to determine the percentage of sperm cell viability and morphological abnormalities (20). Abnormal head and tails were evaluated according to (21).

- **Reproductive organ weights :**

At the termination of the experiment, reproductive organs which include testes and reproductive accessory organs (epididymis, prostate gland, seminal vesicle) were dissected out, trimmed off the attached
tissue, after that weighed and record their weights.

- **Hormones assay:**

  After light anesthesia with chloroform, the blood was collected from the retro-orbital plexus in a test tube and left to clot then centrifuged. After centrifugation at 3000 rpm for 15 minutes the clear sera were separated for determination of serum levels of testosterone hormone, follicle stimulating hormone (FSH) and Luteinizing hormone (LH) by method mentioned by Teitz (22).

- **Statistical analysis:**

  All the grouped data were statistically reading with SPSS program, version 16 software (2009). Testing methods included one-way analysis of variance (ANOVA) for comparisons between more than two groups followed by least significant difference (LSD) test for comparison between two groups. P-values of ≤ 0.05 were considered to record statistical significance. All the data were expressed as mean ± standard error.

**Results**

The result of present study revealed that administration of acrylamide substance orally in dose (150 mg / Kg BW) in male rats induced significant decrease at (p<0.05) in the sperm characteristics (sperm concentration, sperm motility, viability, normal sperm) (60.02±0.98 , 35.90±1.2 , 0.97±0.11 , 37±1.90 ) respectively compared with control group ( 89.11±1.1 , 69.81±0.62 , 2.41±0.17 , 75.81±1.32 ) in the same time induced significant increase at (p<0.05) in the sperm abnormalities (12.3±0.96) compared with control group (5.2±0.36) while co-administration of local propolis extract to acrylamide treated group rats showed a significant increase in the sperm characteristics toward the control values (87.71±1.90 , 69.30±0.17 , 2.37±0.18 , 74.93±0.96) and a significant decrease in the sperm abnormalities (9.1±0.83) compared with acrylamide treated group table (1).

**Discussion**

Propolis has attracted researchers’ several biological and pharmacological interest in the last decades because of its properties, such as immunomodulatory,
antitumor, antimicrobial, antiinflammatory, antioxidant, among others (23). Besides, propolis-containing products have been intensely marketed by the pharmaceutical industry and health-food stores (24). Propolis rich in variety of biological active substances have highly activity against oxidative stress inducing by free radicals and reactive oxygen spices (25). Acrylamide is an important industrial chemical primarily used in the production of polyacrylamide and as a chemical intermediate in the synthesis of a variety of other chemicals. The discovery of acrylamide in a variety of human foods including heat processed starchy foods such as potato chips and bread has been reported. Acrylamide have reproductive toxicity (4) neurotoxicity (3) clastogenicity (26), and mutagenicity in somatic and germ cells (27) It is also a toxicant of the male reproductive system in rodents, but very little evidence is available about its toxic effects on the female reproductive system (28) The toxicities of Acrylamide in male animals include degeneration of the epithelial cells of the seminiferous tubules, decreased number of sperm, and increase abnormal sperm and result in decreased fertility rates and retarded development of pups, as well as decrease levels of sex hormones (29). It promotes biological oxidation both in vitro and in vivo because of its pro-oxidant activity (30) Testicular oxidative stress appears to be a common feature in much of what underlies male infertility, which suggests that there may be benefits to develop better antioxidant therapies for relevant cases of hypospermatogenesis (31). The present study aimed to investigate protective effects of local propolis extract on testicular toxicity of acrylamide in male albino rats. To our knowledge this is the first study that evaluate the protective role of local propolis extract on testicular damage induced by acrylamide in experimental animals. Sperm characteristics as sperm concentration, motility, rate of viability, normal and abnormal sperm count considered as an important factors for the identification of the normal function of the testes (32). The present results showed that oral administration of acrylamide (150 mg/kg B.W) cause highly significant reduction in the sperm parameters compared with control group rats, this result confirmed other pervious studies, where acrylamide use was associated with decreased sperm count motility(%) , rate of viability (%) and increased dead and abnormal sperm count (33,34,35) this reduction in the sperm parameters may be ascribed to lowering in the serum testosterone levels which induced by acrylamide uptake which leading to degeneration of seminiferous tubules with sloughing of seminferous epithelium and spermatogenic cells (36) adequate level of testosterone in testes is critically required for normal spermatogenesis, maintenance of sperm morphology and normal physiology of somniferous tubules (37) Co-administration of local propolis extract to acrylamide treated group rats restored the sperm characteristics towards normal values which may be returned to restored in the serum testosterone levels which reflect positively on the sperm characteristics (38) in addition to anti-oxidative effectiveness of propolis mainly its flavonoids and phenolic content that is capable of scavenging free radicals and thereby protective against lipid peroxidation which can be produced by acrylamide (39). Such improvements in the semen characteristics by propolis collected from different region agree with previously reported benefits of propolis supplementation of sperm quality and male fertility of rats (39,40). On the other hand, our results indicated that administration of acrylamide alone induced significant reduction at (p<0.05) in the absolute weights of testes and accessory reproductive organs (epididymis, prostate and seminal vesicle) compared with control group rats, this can be occur due to diminishment in number of germ cells, atrophy of Leydig cells and lower
rates of spermatogenesis, because weight of the testes largely depends on the mass of the differentiated spermatogenic cells. Memorably, testicular mass is a valuable index of reproductive toxicity in male animals (41). Decrease in these parameters was consistent with elimination of germ cells (42). So co-administration of local propolis extract to acrylamide treated rats restored the testes weights and other reproductive organs towards normal which may be returned mainly due to antioxidant activity of propolis extracts (43). Testosterone considered as a key hormone that plays an important role in the regulation of spermatogenesis. Acrylamide administration induced significant decrease at (p<0.05) in levels of serum testosterone and other studied hormones (FSH, LH) compared to control group rats. Whereas it was found that co-administration of local propolis extract caused significant differences as compared with untreated acrylamide group rats, this indicator that propolis extract hence testosterone hormone and FSH, LH production and ameliorate sperm production and the process of fertility. The role of propolis on the testosterone and other reproductive hormones has been reported. In previous study performed on the Turkish awassi lambs at weaning time, demonstrated that the administration of the Iranian propolis water extract cause significant elevation in the levels of serum testosterone, FSH and LH compared with control group lambs (44). From the results of present study can be concluded the important role of local propolis extract in protection of male reproductive organs from detrimental effects of acrylamide in male albino rats and minimize its reproductive toxicity.
