Abstract
The present work is a theoretical and experimental study of a biconvex lens as an optical processor. The MATLAB software concerning the Fourier optics is used as the basic numerical tool for these work. In addition to providing functions for calculating Fraunhofer diffraction. The FFT command enables the calculation of the diffraction pattern of an arbitrary aperture. Relatively simple MATLAB® scripts are constructed to calculate the diffraction patterns of arbitrary graphics such as geometry shapes, pictures of faces, letters. This paper also describes a few demonstrations that can be used to reinforce what is covered on the work. The demonstrations are based on a simple (2F set-up) system. Diffraction imaging relies on many other technological innovations, including: a CCD camera, digital camera HD (12 Mega Pixels) with a lens (f=7.23 mm). The experimental results agree with the theoretical calculations.

1- Introduction
Diffraction theory is often taught as a purely mathematical treatment or used to analyze very simplistic apertures such as slits and holes. The effect is a general characteristic of wave phenomena occurring whenever a portion of a wavefront, be it sound, a matter wave, or light, is obstructed in some way. The various segments of the Wavefront that propagate beyond the obstacle interfere, causing the particular energy-density distribution referred to as the diffraction pattern. There is no significant physical distinction between interference and diffraction (Eugene Hecht, 2002). As shown in figure (1).
The goal of this paper is to describe how the scientific analysis tool MATLAB® can be used to perform complex mathematical calculations with Fraunhofer diffraction domains and experimental implementation. Fraunhofer diffraction deals with the limiting cases where the light approaching the diffracting object is parallel and monochromatic, and where the image plane is at a distance large compared to the size of the diffracting object (Okan K. Ersoy, 2007). Fraunhofer diffraction is the far-field approximation, where the observed pattern in the focal plane of a lens. The far-field diffraction, or Fraunhofer diffraction of the Kirchhoff–Fresnel integral have the same mathematical appearance. The only difference is that in far-field approximation the diffraction pattern is observed on a faraway screen, whereas in Fraunhofer diffraction the observation screen is placed at the focal plane of a lens and that may be closer to the aperture (K.D. Moller et al., 2003). Linear transforms, especially Fourier and Laplace transforms, are widely used in solving problems in science and engineering. The Fourier transform is used in linear systems analysis, antenna studies, optics, random process modeling, probability theory, quantum physics, and boundary-value problems (Brigham, E.Oren, 1988) and has been very successfully applied to restoration of astronomical data (Brault, J.W. and White, O.R., 1971).

2- Theory
Fraunhofer diffraction is the theory of transmission of light through apertures under the assumption that the incident wave is multiplied by the aperture function. Fraunhofer diffraction is the far-field approximation, where the observed pattern is located at the focal plane of a lens (Okan K. Ersoy, 2007), which usually called Fourier plane. So, we will use the Fraunhofer approximation to determine the propagation of light in the free space beyond the aperture. As shown in figure (2), in this figure which showing position of Fraunhofer (far field) region (Keigo Iizuka, 2008).

Fig. 1: Arrangement used for observing diffraction of light (Joseph W. Goodman, 1996).
In Fig. (3) where the observed plane wave which is diffracted in one plane. For this wave in the $(x,y)$ plane directly behind the plane $(z=0)$ with the following transmission distribution $\tau(x,y)$ (David Voelz, 2011):

$$E(x,y) = \tau(x,y) \ E_s(x,y)$$  \hspace{1cm} (1)

Where $E_s(x,y)$ : electric field distribution of the incident wave. The further expansion can be described by the assumption that a spherical wave emanates from each point $(x,y,0)$ behind the diffracting structure (Huygens’ principle). This lead to Kirchhoff’s diffraction integral (David Voelz, 2011):

\hspace{1cm}
\[ E(x', y', z) = \frac{1}{i\lambda} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} E(x, y) \frac{e^{i\theta}}{r} \cos (\hat{n}, \hat{r}) \, dx \, dy \]  

with \( \lambda \) = spherical wave length, 
\( \hat{n} \) = normal vector of the \((x, y)\) plane. 
\( k = \text{wave number} = \frac{2\pi}{\lambda}. \)

Equation (2) corresponds to a accumulation of spherical waves, where the factor \( \frac{1}{i\lambda} \) is a phase and amplitude factor and \( \cos (\hat{n}, \hat{r}) \) a directional factor which results from the Maxwell field equations. The Fresnel approximation (observations in a remote radiation field) considers only rays which occupy a small angle to the optical axis \((z-axis)\). In this case, the directional factor can be neglected and the \( \frac{1}{r} \) dependence becomes: \( \frac{1}{r} = \frac{1}{z} \). In the exponential function, this cannot be performed as easily since even small changes in \( r \) result in large phase changes. This results in the Fresnel approximation of the diffraction integral.

\[ E(x', y', z) = \frac{e^{ikz}}{i\lambda} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} E(x, y) \exp \left\{ \frac{ik}{2z} ((x' - x)^2 + (y' - y)^2) \right\} \, dx \, dy \]  

For long distances from the diffracting plane with concurrent finite expansion of the diffracting structure, will obtain the Fraunhofer approximation as given by eq. (4).

\[ E(x', y', z) = C(x', y', z) \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} E(x, y) \exp \left\{ 2\pi i \left( \frac{x'}{\lambda z} x + \frac{y'}{\lambda z} y \right) \right\} \, dx \, dy \]  

with: \[ C(x', y', z) = \frac{e^{ikz}}{i\lambda z} \exp \left\{ \frac{i\pi}{\lambda z} (x'^2 + y'^2) \right\} \]

Where \( C(x', y', z) \) is the phase factor and \( E(x', y', z) \) is the electric field distribution in the plane \((x', y')\) for \( (z = \text{const}) \) (David Voelz, 2011).

3- Theoretical Results

When the distance away from the grating is large or a lens is used to focus the diffraction pattern to the image plane then the diffraction pattern becomes a Fourier transform as given by (Joseph W. Goodman, 1996).
\[ E(x,y,z) = C \mathcal{F}\{E\} \mid_{\frac{x}{\lambda} \frac{y}{\lambda^2} \frac{z}{\lambda^2}} \]  \hspace{1cm} (5)

Where : \( E(x, y, z) \) : is the electric field distribution.

\( C \) : is the phase factor.

\( \nu_x \) and \( \nu_y \) are spatial frequencies.

\( \lambda \) = wave length.

3-1 Fourier Transform using Matlab for rect-function

The one-dimensional (1-D) rectangular function is given by:

\[ \text{rect}(\frac{x}{a}) = \begin{cases} 1, & |x| < a/2 \\ 0, & \text{otherwise} \end{cases} \]  \hspace{1cm} (6)

Where \((a)\) is the domain of the function (or the width of the aperture). The two-dimensional of the rectangular function is given by:

\[ \text{rect}(x/a, y/b) = \text{rect}(x/b) \text{rect}(y/b) \]  \hspace{1cm} (7)

The Fourier transform of the (2-D) rectangular function is given by (Ting Chung Poon, 2007):

\[ \mathcal{F}_{xy}\{f(x,y)\} = \mathcal{F}_{xy}\{\text{rect}(x/a, y/b)\} \]

\[ = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \text{rect}(x/a, y/b) \exp[-2\pi i (\nu_x x + \nu_y y)] dx \, dy \]  \hspace{1cm} (8)

The aperture function, \( \{\text{rect}(x,y)\} \) and its Fourier transform is shown in fig. (4).

Fig. 4 : a - rect-function: gray-scale plot.

Fig. 4 : b - Square-absolute value of Fourier transform of the rect-function: gray-scale plot.
The triangle function is a shape like a triangle, as its name indicates. Figure (5: a) illustrates the wave form. The function can be obtained by the convolution of \( \prod(x) \) with itself as shown (Keigo Iizu, 2008).

\[
\Lambda(x) = \prod(x) * \prod(x)
\]

Using the fact:

\[
\mathcal{F}\{ \prod(x) * \prod(x) \} = \mathcal{F}\{ \prod(x) \} * \mathcal{F}\{ \prod(x) \}
\]

the Fourier transform of eq. (9) is found to be in (Fig. 5: b)

\[
\mathcal{F}\{ \Lambda(x) \} = \sin c^2 f
\]
3-2-1 Fourier Transform of Bitmap Images

When the (2-D) function or image is given with a bitmap file, we can use the m-file given in algorithm (1) to find its Fourier transform. Figure (6:a) is the bitmap image used when the image file of the size is (256×256). It is easily generated with Microsoft® Paint. Figure (6:b) is the diffraction pattern (or the Fourier transform) of the tri-function (Ting Chung Poon, 2007).

Algorithm 1: fft2D bitmap_image.m: m-file for 2-D Fourier transform of bitmap image.

Fig. 6: b- The diffraction pattern (or the Fourier transform) of the tri-function.
3-3 Element Size

The extent of the diffraction pattern is complementary to the size of the single diffracting elements. Figure (8) shows this reciprocal behavior using elliptical apertures of different size (Cetin, A.E., et al., 2004).
Fig. 8: Bitmap images and its transform generated by the m-file in the Matlab software for different size elliptical apertures.

4- Experimental Results

The experimental results include investigation of the Fourier transform by a convex lens for different diffraction objects in a (2F set-up) system. As shown in figure (12).

Fig. 18: Diffraction pattern of triangle aperture as shown by a digital camera HD.

Fig. 19: The power distribution in the triangle aperture as shown by a CCD camera.

Fig. 20: Diffraction pattern of triangle aperture as shown by a CCD camera.
5- Conclusions:

We conclude the diffraction pattern which we calculated with fft2 method, the number of pixels in the diffraction pattern is equal to the number of pixels in the initial image, as shown in figures (4,6,8,9,10,11). Obviously, the total extent of the image is increased without changing the slit or hole width by adding space around the image, which is called zero padding. In figures (13,14,17,18) these figures taken with spatial filter, recorded by a digital camera, from this figures we notice that the intensity pattern observed varies with the distance from the aperture. In figures (5,16,19,20), recorded by a CCD camera, as seen the diffraction pattern depends on the size of aperture or element size. So, the experimental results agree with the theoretical calculations.
